A JOURNAL OF THE
AMERICAN ACCOUNTING ASSOCIATION

AMERICAN ACCOUNTING ASSOCIATION

Board of Directors

President	Gregory B. Waymire, Emory University
President-Elect	Karen V. Pincus, University of Arkansas
Past President	Kevin D. Stocks, Brigham Young University
Vice President	David E. Stout, Youngstown State University
Vice President–Education	Alan Reinstein, Wayne State University
Vice President–Research and Publications	John Christensen, University of Southern Denmark
Vice President–International	Recep Pekdemir, Istanbul University
Vice President–Professional Relations	Kenneth Bouyer, Ernst & Young LLP
Vice President–Sections and Regions	Gail Hoover King, Purdue University Calumet
Vice President–Finance	Stacy E. Kovar, Kansas State University
Vice President–Finance-Elect	Dale L. Flesher, University of Mississippi

The Executive Director of the Association is Tracey E. Sutherland.

The American Accounting Association was founded in 1916 as the American Association of University Instructors in Accounting. Its present name was adopted in 1936. The Association is a voluntary organization of persons interested in accounting education, research, and practice.

Membership in the Association is available at the following annual rates.

Full membership:

Membership dues of $200.00 include *Accounting Education News*, and the online selection of all three Association-wide journals: *The Accounting Review*, *Accounting Horizons*, and *Issues in Accounting Education*. (This does not include Section journals.) Full members may also opt to receive *hardcopies* of AAA journals for an additional cost:

The Accounting Review	with Print Option $35.00	Total U.S. $235.00
Accounting Horizons	with Print Option $15.00	Total U.S. $215.00
Issues in Accounting Education	with Print Option $15.00	Total U.S. $215.00
All three Association-wide journals	with Print Option $65.00	Total U.S. $265.00

Associate membership:

Full-time students are eligible for associate membership. The print option is not available for Associate members.
All three Association-wide journals . . . . U.S. $30.00

In addition, full members may belong to one or more Sections: Accounting, Behavior and Organizations; Accounting Programs Leadership Group; American Taxation Association; Auditing; Diversity; Financial Accounting and Reporting; Forensic and Investigative Accounting; Gender Issues and Worklife Balance; Government and Nonprofit; Information Systems, International Accounting; Management Accounting; Strategic and Emerging Technologies; Teaching, Learning and Curriculum; and Two-Year College. Each Section assesses its own dues, which are collected by the Association.

Editorial correspondence and revisions of manuscripts originally submitted before June 1, 2011 should be sent via email to the incoming Senior Editor, John Harry Evans III, University of Pittsburgh, at tar@katz.pitt.edu • Telephone: (412) 624-8605 • Fax: (412) 648-1693. New manuscripts must be submitted through the Manuscript Submission and Peer Review System, located at http://accr.allentrack.net. The site contains detailed instructions regarding the preparation of files for submission.

The submission fee of $200.00 for members of the AAA or $400.00 for nonmembers may be paid online (VISA or MasterCard only) at https://aaahq.org/AAAforms/journals/tarsubmit.cfm and should be paid before the article is submitted.

Requests for information concerning membership, subscriptions, dues, advertisements, and other matters related to the Association (other than submission of manuscripts) should be sent to the American Accounting Association, 5717 Bessie Drive, Sarasota, FL 34233-2399 • Telephone: (941) 921-7747 • Fax: (941) 923-4093 • Email: Info@aaahq.org. Notice of change of address should be mailed at least eight weeks in advance to ensure undelayed receipt of *The Accounting Review*.

The Accounting Review is indexed in the Social Science Citation Index, which is included in Web of Science.

The Accounting Review (ISSN 0001-4826 print and ISSN 1558-7967 online) is published six times a year in January, March, May, July, September, and November by the American Accounting Association, 5717 Bessie Drive, Sarasota, Florida 34233-2399. General subscriptions are available at the annual rates of $410 for a print copy or at $465 for a print and an electronic copy. The member subscription rate for a hard copy is $35. Electronic access is included with membership dues. Periodicals Postage Paid at Sarasota, Florida and additional mailing offices. **POSTMASTER:** Send address changes to ***The Accounting Review***, 5717 Bessie Drive, Sarasota, Florida 34233-2399.

An Examination of the Cost of Capital Implications of FIN 46

Carolyn M. Callahan

Angela Wheeler Spencer
Oklahoma State University

ABSTRACT: This study examines whether the adoption in 2003 of FASB Interpretation No. 46/R (FIN 46), *Consolidation of Variable Interest Entities—An Interpretation of ARB No. 51,* changed the cost of capital for affected firms. Using comparative analysis on a broad sample of 11,719 firm-quarter observations for 1,389 firms during the period 1998 through 2005, we find evidence that FIN 46 significantly increased the cost of equity capital for firms with affected variable interest entities (VIEs), an increase of approximately 50 basis points relative to firms reporting no material effect from the standard. Further, firms consolidating these formerly off-balance sheet structures experienced the largest increase. Taken together, these results suggest that FIN 46 reduced the opportunity for firms to use off-balance sheet structures to artificially reduce their cost of capital, a matter of regulatory concern.

Keywords: *cost of capital; off-balance sheet; special purpose vehicle; variable interest entity; FIN 46.*

Data Availability: *All data are available from public sources.*

I. INTRODUCTION

In response to Enron and similar accounting scandals, the FASB issued in January 2003, and revised in December 2003, Interpretation 46, *Consolidation of Variable Interest Entities—An Interpretation of ARB No. 51*, FIN 46 and FIN 46R, respectively (hereafter referred to

collectively as FIN 46). Effectively, FIN 46 changed reporting for many off-balance sheet activities, termed variable interest entities (VIEs) under the new standard.[1] Although it increased transparency, FIN 46 was potentially costly to firms, conveying new risks to market participants that could affect the cost of capital. The prior literature regarding the economic impact of this type of mandatory change is mixed (e.g., Khurana 1991; Chen et al. 2010). In recent research, FIN 46 is shown to have real effects on investment activity and product-market competition (e.g., Bens and Monahan 2008) that are theoretically linked to firms' cost of capital. The purpose of this paper is to directly examine the FIN 46 cost of capital impact given the current regulatory and academic debate.

Examining disclosures in annual filings, we identify a sample of 244 firms with off-balance sheet structures impacted by FIN 46 and a control sample of 1,145 firms disclosing no material effect from the standard. Examining 11,719 firm-quarter observations over the period 1998 to 2005, we provide evidence that FIN 46 significantly increased the cost of equity capital for firms with affected VIEs, producing an average increase of approximately 50 basis points relative to the control sample. Further, firms that consolidated these formerly off-balance sheet structures experienced the largest increase following adoption.

Firms have long used off-balance sheet entities to obtain financing and avoid reporting debt on their balance sheets.[2,3] Advocates argue that these structures benefit investors by allowing management to access additional sources of financing, reduce risk, and lower firms' cost of capital. Critics, however, charge that these arrangements are mainly driven by accounting, not economic considerations and any reduction in the cost of capital is artificial (Reason 2002). Recent corporate scandals likewise suggest these entities can be used opportunistically by firm managers, with sponsoring firm investors remaining generally unaware of underlying risks.

The stated purpose of FIN 46 was to "achieve more consistent application of consolidation policies . . . [and] provide more complete information about the resources, obligations, risks, and opportunities of the consolidated enterprise" (FASB 2003, 4). Proponents of FIN 46 argued that gains in investor confidence counteracted any additional cost. Conversely, critics argued FIN 46 conveyed new, unsubstantiated risks to market participants and the complexity and opaqueness of FIN 46 offset any informational gains.[4]

Theoretically, in a frictionless market, FIN 46 should not affect firms' cost of capital as long as, upon adoption, investors perceive no change in expected cash flow and risk posture. In fact, increased transparency may lower firms' cost of capital (e.g., Botosan and Plumlee 2002). Departing from the theory of frictionless markets, other evidence suggests costs to investors could increase under a mandated standard such as FIN 46 (for instance, see evidence in Khurana [1991] regarding SFAS 94).

---

[1] FIN 46 introduced the term "variable interest entities" to distinguish those entities from other off-balance sheet activities not subject to FIN 46. In this paper, we use the term VIE when discussing off-balance sheet activities subject to FIN 46 and we use the broader term "special purpose vehicles" (SPVs) otherwise.

[2] Besides their reporting advantages, these entities often isolated risk, in part because they were considered "bankruptcy remote" as the assets of the off-balance sheet entity were protected from bankruptcy proceedings if the sponsor declared bankruptcy. This isolation often allowed firms to obtain lower cost financing (Reason 2003).

[3] Structures involving off-balance sheet financing include various operating leases or operating guarantees; sale and leaseback transactions; real estate investment trust financing; public or private joint ventures; research and development partnerships; sale of receivables with recourse; and bank financial instruments such as guarantees, letters of credit, and loan commitments (Mills and Newberry 2005).

[4] The ongoing debate regarding proper accounting for off-balance sheet structures provides evidence of the continuing interest in and complexity of this issue. Most recently, SFAS 166, *Accounting for Transfers of Financial Assets—An Amendment of FASB Statement No. 140*, and SFAS 167, *Amendments to FASB Interpretation No. 46(R)*, alter accounting treatment for these structures.

The *Wall Street Journal* (2003) noted FIN 46 could require firms to consolidate as much as $500 billion in assets and liabilities, and some financial analysts warned these changes could "affect almost every line in the financial statements" (Credit Suisse 2003, 1), thereby potentially affecting loan covenants, credit ratings, and regulatory capital requirements. Practitioners further noted FIN 46 was "likely to raise the cost of capital and otherwise create additional costs for companies that may flow through to shareholders" (KPMG 2003, 6).

In short, firms that consolidated and/or disclosed VIEs potentially incurred costs associated with increased estimation risk, significant restructuring and/or adoption costs, and more reported leverage than before. Further, firms avoiding consolidation of VIEs upon adoption of the standard often incurred additional costs to restructure or divest their VIEs, and financial institutions that arranged/held VIEs often sought to avoid FIN 46 requirements.[5] FIN 46 adoption could affect future cash flows by constraining debt contracting options and forcing firms to incur additional costs, thereby raising investor concern about firms' information risk.[6] Each of these can increase the cost of capital.

Given the arguments, the economic impact of FIN 46 on investors' perceptions and firms' cost of capital is an empirical question. Taken together, the theory and potential economic effects lead to the following question: Did FIN 46 influence firms' cost of capital? In other words, prior to the implementation of FIN 46, were investors bearing the cost of hidden risk through overpriced equities? We find, relative to a control group of firms disclosing no material effect from FIN 46, affected firms experienced an increased cost of equity following adoption of the standard, with firms consolidating VIEs generally experiencing the greatest impact.

Our study contributes to the literature on the cost of capital implications of financial disclosure, the impact of mandated accounting change, and the use of SPVs. Although prior theoretical and empirical research (e.g., Healy and Palepu 2001; Barth and Schipper 2008) suggests increased disclosure lowers firms' costs of capital, we present a context where increased disclosure results in higher cost of equity capital, similar to Ashbaugh-Skaife et al. (2009). Our findings are also consistent with Lambert et al.'s (2007) argument that mandated disclosures affect firms differentially, depending on the ramifications for future cash flows. It may also be argued that the pre-FIN 46 reporting paradigm enabled some firms to reduce their cost of capital and FIN 46 rectified this understatement.[7] Finally, we provide new evidence on the consequences of SPV use. Feng et al. (2009) document prevalent use of those activities and link their use to earnings management; we show the implications for the cost of capital, which may be of concern to both managers and regulators. Furthermore, our findings may inform the ongoing discussion of regulatory issues related to off-balance sheet structures.[8]

Section II next provides background on FIN 46 and develops hypotheses. Section III describes our sample. Section IV describes our research design. Section V describes the results and section VI concludes.

---

[5] Bens and Monahan (2008) present evidence that the volume of asset-backed commercial paper (ABCP) began to decline when FIN 46 was first proposed, and this decline is primarily attributable to a reduction in North American banks' sponsorship of ABCP. They also demonstrate North American banks entered into "costly" restructuring arrangements to avoid consolidation of their conduits according to the new accounting standards, suggesting FIN 46 appears to have real effects on investment activity and product-market competition that are theoretically linked to firms' cost of capital.

[6] By "information risk," we mean the likelihood that firm-specific information that is pertinent to investor pricing decisions is of poor quality (Francis et al. 2005b, 29).

[7] We thank an anonymous reviewer for illustrating this point with the Enron case. It is plausible that FIN 46 requirements would have affected Enron's disclosures. Perhaps it would have increased Enron's cost of capital in the short term (i.e., lowered its stock price), but this could have had the longer-term impact of decreasing the cost of capital by avoiding a financial collapse.

[8] For example, consider the recent issuance of SFAS 166, *Accounting for Transfers of Financial Assets—An Amendment of FASB Statement No. 140*, SFAS No. 167, *Amendments to FASB Interpretation No. 46(R)*, and the in-process joint project of the IASB and FASB, *Consolidation: Policy and Procedures*.

II. BACKGROUND AND DEVELOPMENT OF HYPOTHESES

FASB Interpretation Number 46 (FIN 46)

FIN 46 defined "variable interest entities" as thinly capitalized entities with equity interests insufficient to finance the operations of the entity and not possessing the usual relationship between ownership, control, and risk.[9] The Interpretation established a new consolidation model based on sharing of economic risk that applied to a wide array of previously unconsolidated entities (PricewaterhouseCoopers 2004). Under this new model, the firm exposed to the majority of expected losses or residual rewards is deemed the primary beneficiary and must consolidate the entity, regardless of equity ownership (FASB 2003, ¶14). FIN 46 also established new disclosure requirements for all owners of significant variable interest in VIEs, including primary beneficiaries (FASB 2003).[10] The standard, however, did not apply to all firms or even all SPVs. Among others, it specifically excluded qualifying special purpose entities (QSPEs) subject to the reporting requirements of FAS 140 (FASB 2003, ¶4).[11]

Impact of FIN 46 on Cost of Capital (H1)

For firms with SPVs, FIN 46 could result in no change, a decrease, or an increase in the firm's cost of capital. Theoretical and empirical support exists for each of these outcomes. Theoretically, in perfect and frictionless markets, a mandated accounting change will have no effect on the cost of capital unless the change shifts a firm's risk profile and expected cash flows. Proponents of this "no effect" outcome argue that informed investors were aware of SPVs prior to adoption of FIN 46.[12] Further, some prior research suggests that the market can see through the structure of off-balance sheet items and price associated risk efficiently (Bauman 2003; Jin et al. 2006). Thus, it is possible that firms with SPVs experienced no change in cost of capital post-FIN 46.

In contrast, increased transparency required by FIN 46 may *decrease* firms' cost of capital following adoption. Increased transparency afforded by increased disclosure could decrease the adverse selection problem and improve liquidity, thereby lowering cost of equity through greater demand for a firm's securities and/or reduced transaction costs (Amihud and Mendelson 1986; Diamond and Verrecchia 1991; Easley and O'Hara 2004). Further, the estimation risk literature predicts disclosure leads to increased transparency, generating lower cost of equity (e.g., Barry and

---

[9] Specifically, these are structures in which "the total equity investment at risk is not sufficient to permit the entity to finance its activities without additional subordinated financial support" (FASB 2003, ¶5a); at-risk equity holders do not have the usual rights and obligations of shareholders (e.g., voting rights, obligations to absorb losses, and right to receive residual returns) (FASB 2003, ¶5b); or "the voting rights of some investors are not proportional to their obligations to absorb the expected losses of the entity, their rights to receive the expected residual returns, or both" (FASB 2003, ¶5c).

[10] Primary beneficiaries are required to disclose the nature, purpose, size, and activities of VIEs and information about assets pledged as collateral for the VIE's obligations. All other firms with significant interests in VIEs are also required to disclose the nature, purpose, size, and activities of the VIEs, the nature of their involvement with the VIE, and their maximum exposure to loss.

[11] QSPEs were granted this scope exception largely because of the passive, pass-through structure mandated by FAS 140. However, as the credit crisis unfolded through 2007 and 2008, many of these structures began to require active management, in particular through restructuring of associated loans. In discussing the subsequent removal of the QSPE exception, FASB Chairman Herz noted in 2008, "QSPEs were originally intended as passive entities but morphed into something different. Unfortunately, it seems that some folks used Qs like a punchbowl to get off-balance sheet treatment while spiking the punch. That has led us to conclude that now it's time to take away the punchbowl" (Herz 2008, 11). As the credit crisis revealed, the scope exception granted to QSPEs proved to be an important issue. For instance, Blundell-Wignall et al. (2009) estimated over $3 trillion in QSPEs remained off-balance for the 19 U.S. Supervisory Capital Assessment Program (SCAP) banks at the end of 2008.

[12] Certain structures had standard disclosure (e.g., synthetic leases reported as operating leases) and firms must list subsidiaries, including many SPVs, in Exhibit 21 of the SEC 10-K.

Brown 1985; Lambert et al. 2007; Barth and Schipper 2008).[13] Several empirical studies likewise link expanded disclosure policy to lower cost of equity capital (Botosan 1997; Botosan and Plumlee 2002; Francis et al. 2005a).

Finally, FIN 46 could potentially *increase* firms' costs of capital through the direct and indirect effects described in Lambert et al. (2007). They show higher quality disclosures directly affect the firm's assessed covariances with other firms' cash flows and corresponding cost of capital. Further, these effects can either increase or decrease costs of capital, depending on the expected value of the firm's future cash flows and the covariance of those cash flows with the sum of all cash flows in the market.

A change in disclosure requirements can also indirectly affect the cost of capital by changing a firm's real decisions. Some firms that are the primary beneficiaries of VIEs under FIN 46 incurred significant FIN 46 implementation costs and other firms chose to incur costs to dispose of, restructure, or terminate VIEs to avoid consolidation (KPMG 2003; Credit Suisse 2003). Such restructuring charges may represent continuing costs because one solution to preserve off-balance sheet treatment was to shift VIE consolidation to a third party, with corresponding, ongoing costs for such services (Bens and Monahan 2008). Consolidating off-balance sheet structures also affected financial ratios, thereby constraining debt capacity and in some cases triggering renegotiation of debt covenants (Credit Suisse 2003). Thus, FIN 46 could change management decisions and affect future cash flows by restricting future contracting and financing options. In similar circumstances in connection with changes required by SFAS 94,[14] Khurana (1991) argues that consolidation of non-homogeneous subsidiaries could interfere with the ability of the firm to raise debt capital in the future and also reduce firms' opportunity sets for accounting, financing, production, and investment decisions. Similarly, Livdan et al. (2009) show that financing constraints inhibit firms' ability to smooth dividend streams when faced with aggregate shocks. We therefore test the following hypothesis:

> **H1:** Firms with VIEs experienced a change in cost of capital after FIN 46 compared to firms not materially affected by the standard.

Differential Impact of Consolidating or Divesting VIEs on Cost of Capital (H2)

We next analyze whether actions that firms took with respect to their VIEs could differentially affect cost of capital post-FIN 46. FIN 46 generally requires the primary beneficiary of the VIE to consolidate the previously off-balance sheet entity; however, some firms responded by divesting, restructuring, or otherwise terminating relationships with those structures. By keeping VIEs off-balance sheet, firms could preserve greater financial flexibility and avoid violating debt covenants, thereby limiting the impact of FIN 46. For example, Bens and Monahan (2008) show that banks generally sought to avoid consolidation of asset-backed commercial paper conduits by reducing the number of new commercial paper SPVs and by restructuring existing VIEs so that separate entities held the residual interests. Such actions prevented an adverse impact on accounting ratios and credit ratings post-FIN 46. Importantly, those firms that take actions to preserve off-book treatment of their VIEs imply there is some economic advantage to keeping these structures off-book. However, any restructuring required to retain this off-book treatment may be costly, reducing the benefits associated with the VIE in question. Conversely, firms that consolidated VIEs following FIN 46 presumably did so because the VIEs are economically profitable for the firm, despite any corresponding increase in reported liabilities and associated effects.

---

[13] In our context, "estimation risk" is investor uncertainty about the parameters of the cash-flow-generating process (e.g., Lewellen and Shanken 2002). This uncertainty is closely related to information risk, which is the quality of firm-specific information pertinent to investor pricing decisions (e.g., Francis et al. 2005b).

[14] SFAS 94 (*Consolidation of All Majority-Owned Subsidiaries: An Amendment of ARB No. 51 with Related Amendments of APB Opinion No. 18 and ARB No. 43*) concerns the consolidation of non-homogenous subsidiaries, while SPEs often involve activities central to the operations of the parent firm (Maines et al. 2003). Thus, although the impact of these two standards is not expected to be identical, evidence from the impact of SFAS 94 should be generally informative about the market treatment of off-balance sheet structures.

The preceding considerations suggest two potential effects on the cost of capital: (1) an indirect effect that these economically necessary VIEs have on future cash flows, and (2) a direct effect due to increased disclosure required by FIN 46, including the potentially greater transparency afforded by consolidation. Regardless of FIN 46's impact on firms' cost of capital, we expect the impact to vary across firms consolidating VIEs compared to those that otherwise kept those structures off their books.

Barth et al. (2003) show that recognized and disclosed amounts contribute to different levels of price informativeness, which may affect estimation risk. Consolidation may also constrain future financing and contracting ability (Khurana 1991) and ability to smooth cash flows (Livdan et al. 2009). We therefore expect that FIN 46 affects the cost of capital for consolidating firms differently than for firms that did not consolidate, suggesting our second hypothesis:

> **H2:** FIN 46 affected the cost of capital differently for firms that consolidated information pertaining to VIEs compared to firms that divested or restructured VIEs.

III. SAMPLE SELECTION AND DESCRIPTION

Identifying Firms With and Without VIEs

We gathered our sample from disclosures made within firms' annual filings using procedures similar to, but broader in scope than Zechman (2010). Given the relative lack of disclosure about VIEs prior to adoption of FIN 46, we also restricted our hand-gathered sample using the procedures of Feng et al. (2009).

First, we identified firms specifically making disclosure(s) related to FIN 46. To gather data on such firms, we used 10-K Wizard to search annual reports filed in 2004, primarily for the fiscal year ending 2003.[15] We searched for all occurrences of "FIN 46" and "variable interest entity/entities" in these filings. This process produced 551 FIN 46 mandated disclosures from 352 firms. We classified these disclosures by whether the firm reported the VIE on a consolidated basis after FIN 46 adoption and by the purpose of each VIE. Table 1 provides a breakdown of this group, and sample disclosures are provided in Appendix A. As part of this data gathering procedure, we also identified 1,753 firms that reported "no material effect" or "no effect" from FIN 46 or FIN 46(R), but provided no further details about associated VIEs.[16]

---

[15] Since FIN 46 was adopted in January 2003, the first 10-K reports referencing FIN 46 were filed with the SEC in early 2003. FIN 46 was subsequently superseded by FIN 46(R), which was issued in December 2003. FIN 46(R) changed a number of requirements but did not alter the basic thrust of FIN 46. Although our primary sample of interest is composed of firms that adopted FIN 46/FIN 46(R) for fiscal years ending in 2003, FIN 46(R) allowed staggered effective dates; as a result, not all public firms had adopted the new provisions for VIEs for the fiscal year ending in 2003. Specifically, while firms had to adopt either FIN 46 or FIN 46(R) for the first reporting period ending after December 15, 2003, some entities have year-ends earlier than December 15. Further, if firms applied FIN 46 for fiscal years ending in 2003, they had an extended deadline to apply FIN 46(R) in the first reporting period ending after March 15, 2004. Small business issuers had a further extended deadline to apply FIN 46(R) in periods ending after December 15, 2004.

[16] While it is not possible to know with certainty why firms would disclose no material effect from a recent standard, professional guidance provides two possibilities. Given the staggered adoption dates of FIN 46 and FIN 46(R) (see footnote 15), it is possible that firms had not fully adopted the standard; in fact, some indicate this is the case. For standards issued but not yet adopted, SAB 74 states, "In those instances where a recently issued standard will impact the preparation of, but not materially affect, the financial statements, the registrant is encouraged to disclose that a standard has been issued and that its adoption will not have a material effect on its financial position or results of operation" (footnote 3). Professional auditing guidance likewise indicates, "If an accounting change has no material effect on the financial statements in the current year, but the change is reasonably certain to have substantial effect in later years, the change should be disclosed in the notes to the financial statements (AU Section 420.20)."

TABLE 1

Description of Sample Firms, Types of VIEs, FIN 46 Compliance, and Industry Affiliations

Panel A: Counts of Firms by Category Based on Use of VIEs and Compliance with FIN 46

Category	Firms Identified (n)	Firms in Final Sample (n)
1. Firms complying with FIN 46 (*F46*)	352	244
2. Firms reporting no material FIN 46 effect (*No_F46_Impact*)	1,753	1,145
Totals	2,105	1,389

Panel B: Types of VIEs and Actions Taken to Comply with FIN 46

	Action Taken					
	On Books		Off Books		Total	
Types of VIEs	n	Percent	n	Percent	n	Percent
Financial VIEs	48	33%	33	34%	81	33%
Operating VIEs	63	43%	52	53%	115	47%
Other VIEs	3	2%	2	2%	5	2%
Multiple Types	32	22%	11	11%	43	18%
Totals	146	100%	98	100%	244	100%

Panel C: Counts of Firms by Industry and FIN 46 Firm Categories

Industry	Description	*No_F46_ Impact* Firms	*F46 Firms*
1	Food	27	7
2	Mining and Minerals	10	1
3	Oil and Petroleum Products	43	7
4	Textiles, Apparel, and Footwear	26	2
5	Consumer Durables	29	7
6	Chemicals	12	6
7	Drugs, Soap, Perfumes, and Tobacco	38	4
8	Construction and Construction Materials	29	16
9	Steel Works, etc.	16	1
10	Fabricated Products	7	2
11	Machinery and Business Equipment	170	21
12	Automobiles	13	4
13	Transportation	44	12
14	Utilities	17	16
15	Retail Stores	81	19
16	Banks, Insurance Companies, and Other Financials	199	54
17	Other	384	65
Total		1,145	244

(continued on next page)

TABLE 1 (continued)

Panel A shows the counts of firms in each firm category: (1) firms that complied with FIN 46 according to disclosures in their 10-K reports; and (2) firms reporting that FIN 46 had no material effect. The number of firms in the final sample reflects firms with at least one implied cost of equity capital measure.

Panel B shows the counts of F46 firms that consolidated VIEs or otherwise brought VIEs onto their books and firms that took actions to keep VIEs off their books (e.g., restructuring, terminating) and the counts in each of four types of VIEs: (1) Financial (lease or finance VIEs); (2) Operating (alliances, affiliates, or joint ventures); (3) Other (trust-preferred securities or multiple unspecified bundles of VIEs), and (4) Firms reporting multiple types of VIEs.

Panel C recaps the number of firms in each firm category by industry. We use Fama and French industry definitions. Firms are categorized as described in Panel A of this table.

Next, for the sample, we used Feng et al.'s (2009) search process to verify the presence or absence of likely VIEs or SPVs in Exhibit 21 of Form 10-K. Feng et al. (2009) document the widespread use of SPVs by utilizing filings made with the SEC related to affiliates.[17,18] Feng et al. (2009) identify likely SPVs as those subsidiaries and affiliates listed in Exhibit 21 with names that contain "Limited Partnership," "L.P.," "LP," "LLC," "L.L.C.," or "trust," since SPVs are typically organized as one of those legal structures. Given inconsistent disclosure before FIN 46, it may be that VIEs organized via one of these common legal structures were more likely to be identified by market participants prior to adoption of FIN 46.[19] Absent voluntary disclosure, VIEs structured by other means may have been difficult to identify prior to adoption of FIN 46. As a result, we further restrict our hand-gathered sample by requiring that firms disclose at least one likely VIE in Exhibit 21 before adoption of FIN 46.[20] By placing this constraint on our sample, we bias against finding a change in cost of capital post-FIN 46, as our main sample includes only those firms with the most obvious, and therefore most likely understood, VIEs before FIN 46.

Categories of Firms in the Sample

We then used firm Central Index Keys (CIKs) to gather corresponding Compustat data and data necessary to estimate valid proxies for implied cost of equity capital as discussed in the next

---

[17] SEC regulations require that firms list subsidiaries and affiliates in Exhibit 21 to their annual 10-K. Specifically, U.S. Federal Regulations (Regulation S-X) 17CFR 229.601(a) specify that public filers submit Exhibit 21, Subsidiaries of the Registrant, as part of the annual 10-K. U.S. Federal Regulations (Application of Regulation S-X) 17 CFR part 210.1-02(x) define a subsidiary as "an affiliate controlled by such person directly, or indirectly through one or more intermediaries" with control defined in 17 CFR part 210.1-02(g) as "the possession, direct or indirect, of the power to direct or cause the direction of the management and policies of a person, whether through the ownership of voting shares, by contract, or otherwise." In other words, subsidiaries in Exhibit 21 may include entities not consolidated under the provisions of U.S. GAAP pre-FIN 46.

[18] Based on our sample-gathering procedures, the Feng et al. (2009) sample appears to include at least some structures that were not VIEs affected by FIN 46, (e.g., exempted structures such as QSPEs or entities such as active LPs and LLCs that are not SPVs).

[19] For example, upon its adoption of FIN 46, ConAgra Foods, Inc. disclosed detailed information about multiple VIEs impacted by the standard. A search of the firm's prior-year filing, however, reveals no obvious indication of off-balance sheet structures (e.g., keywords such as "special purpose entity" "off-balance sheet" or "synthetic lease" do not appear within the report), but four likely SPVs (following the Feng et al. [2009] criteria) appear in Exhibit 21.

[20] To replicate the search process of Feng et al. (2009), we use the proximity search feature within directEDGAR© to identify which firms listed in Exhibit 21 subsidiaries or affiliates with names containing the terms identified by Feng et al. (2009). Additionally, but consistent with their intent, we also searched for Exhibit 21 entries using the terms "limited," "ltd.," "ltd," "ltda," or "limitada" both to broaden our search and capture similar terms in Spanish and Portuguese. After the proximity search, we used tools in directEDGAR© to manually examine each Exhibit 21 to confirm the results. Because Feng et al. (2009) note that firms sometimes list subsidiaries in Exhibit 22 rather than 21, we also included this exhibit in our search. As such, this component of our procedure represents only a refinement to the process of Feng et al. (2009) in that we expand the keyword set used.

section. After identifying sample firms as described above and verifying data availability, we formed two categories as follows:

1. *F46* firms are those 244 firms that disclosed an effect from FIN 46 and were verified to have likely SPVs disclosed in Exhibit 21; and
2. *No_F46_Impact* firms are those 1,145 firms that disclosed that FIN 46 had no material effect on their financial results.[21]

Panel A of Table 1 describes our final sample of 1,389 firms. Panel C of Table 1 reports the sample firm groups according to Fama and French industry classifications. As this panel shows, firms across both sample categories are concentrated in the Fama and French "other" category. However, in the "machinery and business equipment" group, more firms report no effect from FIN 46 than disclose an effect from FIN 46.

Categories of F46 Firms According to the Compliance Action Taken

To examine H2, as reported in Panel B of Table 1, we further categorized *F46* firms according to the action taken in response to the standard. We categorize firms by whether they (1) brought the VIEs onto their books (*on books*) by consolidation, purchase of assets, etc. or (2) did not bring VIEs onto their books (*off books*) because the firm was not the primary beneficiary, restructured its interest in the entity, etc. Panel B shows that 146 *F46* firms brought VIEs onto their books and 98 firms did not.

Categories of VIEs for FIN 46 firms

Panel B of Table 1 also shows the breakdown of the *F46* firms according to the type of VIE reported. Approximately one-third of firms reported financial VIEs, almost half the F46 firms reported operating VIEs, and 18 percent of *F46* firms reported multiple types of VIEs. We separately categorize firms with multiple types, since it is difficult to determine the dominant VIE type for those firms. In general there is little difference in the types of VIEs brought onto books compared to those kept off books. However, firms with multiple types were more likely to bring at least one VIE onto their books.

IV. RESEARCH METHODS, IMPLIED COST OF EQUITY PROXIES, AND EMPIRICAL MODELS

Defining the Pre- and Post-FIN 46 Periods

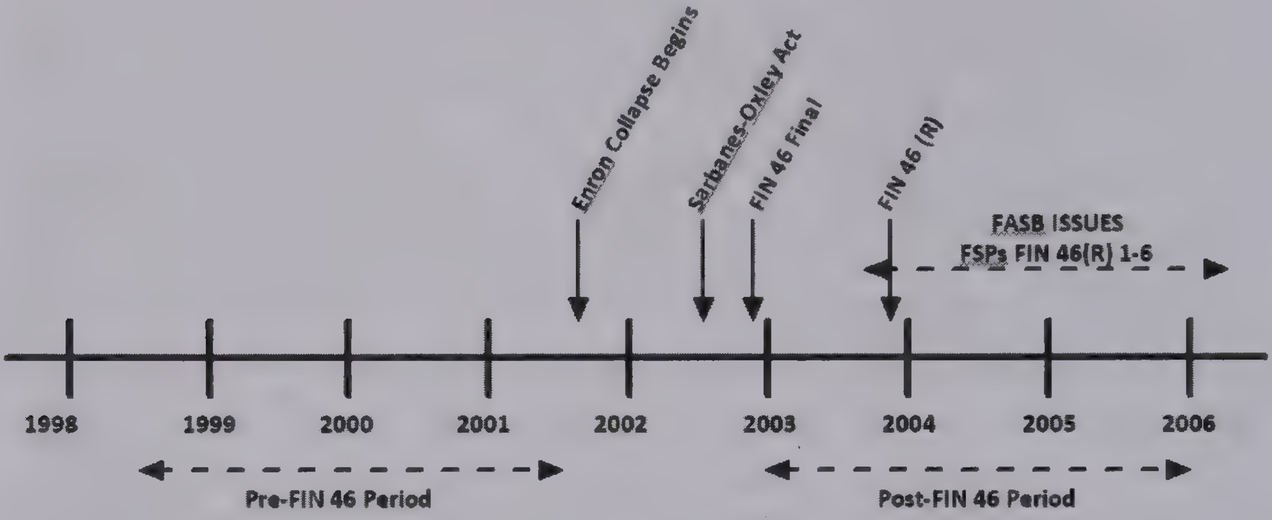
Our goal is to examine changes in implied cost of equity capital following the adoption of FIN 46. However, for many firms that adoption took place over several months or even over multiple years, as FIN 46 was issued and subsequently revised. Thus, there was likely some delay while analysts incorporated information into their estimates.

Firms issued the first financial statements under FIN 46 early in calendar year 2003, and we expect the full effect of FIN 46 to be reflected in sample firms' cost of equity capital measures within 36 months as firms take actions to consolidate VIEs, make required disclosures, or reduce

---

[21] While it is entirely possible that this group restructured VIEs so that FIN 46 would have no material effect on the firm, it is not possible to determine this from the disclosure provided within the annual report. We separate these firms because, considering the regulatory guidance discussed above, by making disclosures of this type, it is possible that these firms expect their use of VIEs may have a material effect in future periods, thus altering the current risk position.

FIGURE 1
Timeline



This figure presents a timeline of important and relevant events leading up to and following the issue of FIN 46, and it shows our control period, the pre-FIN 46 time period, and our focus for this research, the post-FIN 46 time period. We define the pre-FIN 46 period as the 3rd calendar quarter of 1998 through the 2nd calendar quarter of 2001 and the post-FIN 46 period as the 1st calendar quarter of 2003 through the 4th calendar quarter of 2005. We exclude the transitory period beginning the 3rd calendar quarter of 2001 and ending the 4th calendar quarter of 2002. FSP indicates FASB Staff Position document.

their participation in VIEs. We therefore define the post-FIN 46 time period as the 36-month period from the first calendar quarter of 2003 through the fourth quarter of 2005.

As a benchmark, we compare firms' cost of equity capital against a similar pre-FIN 46 period.[22] Since Enron Corporation's collapse began in the Fall 2001 and the FASB's initial development of FIN 46 took place during 2002, those events could affect the cost of equity capital for firms that participated in VIEs and confound any comparison. Thus, we exclude from analysis firm-quarter observations for the 18 months beginning in the third calendar quarter of 2001 and ending in the fourth calendar quarter of 2002.[23] We therefore define the pre-FIN 46 time period as the 36 months immediately preceding that transitory period, beginning in the third calendar quarter of 1998 and ending in the second calendar quarter of 2001. We expect that measures of cost of equity capital during this time period were untainted by the notoriety generated by Enron's collapse and subsequent actions by the FASB to change treatment of special purpose entities. Figure 1 graphically portrays important events, such as the collapse of Enron and the adoption dates of FIN 46 and FIN 46(R), in relation to the pre- and post-FIN 46 periods.

Proxies for the Implied Cost of Equity Capital

We employ multiple accounting-based proxies for firms' implied cost of equity capital that are widely used in recent finance and accounting literature (see Botosan and Plumlee [2005] for a detailed discussion). We select these accounting-based proxies because they are forward-looking measures of expected returns. Furthermore, these proxies rely on analysts' estimates of future firm performance, and given the complexity of these structures and the limited disclosure about firms' involvement with VIEs prior to FIN 46, analysts should be well positioned to assess the impact of VIEs on firm performance both before and after FIN 46.

---

[22] We also tested shorter (one-year and two-year) pre- and post-FIN 46 periods with consistent results.

[23] The implications of our analyses are generally unchanged if we include these 18 quarters. However, we find substantial variation in estimates of implied cost of equity capital during this period consistent with the level of uncertainty connected with the Enron scandal and the prospective regulation of VIEs.

Consistent with prior research (e.g., Li 2010; Hail and Leuz 2006, 2009; Dhaliwal et al. 2007), our primary dependent variable is the average of four proxies. Ogneva et al. (2007), Chen et al. (2010), and Hail and Leuz (2006) all advocate the use of multiple measures to ensure that results are robust to method choice; for this reason we also present results for multiple measures.[24]

First, we use the proxy based on Easton's (2004) PEG ratio since Botosan and Plumlee (2005) find this measure to be predictably and consistently related to other risk measures. Additionally, we use the proxy based on Ohlson and Juettner-Nauroth (2005), since Gode and Mohanram (2003) find that this proxy is reliably related to other risk measures as well as *ex post* returns. We also use proxies developed by Gebhardt et al. (2001) and Claus and Thomas (2001), which are based on residual income valuation models (e.g., Ohlson 1995) and widely used in other accounting research (e.g., Li 2010; Dhaliwal et al. 2007; Daske 2006; Hail and Leuz 2006, 2009; Hribar and Jenkins 2004). For each of the cost of equity capital measures, we use the last analyst earnings per share and long-term growth estimates from I/B/E/S in the calendar quarter and market prices as of the end of the quarter, consistent with Dhaliwal et al. (2007). We describe the calculation of each of these proxies in Appendix B.

Defining Control Variables for Analysis of Implied Cost of Equity Capital

Prior research examining implied cost of equity capital employs a broad set of control variables.[25] Until recently, little theory has been available to guide the choice of control variables. However, Hughes et al. (2009) demonstrate the difference between the implied cost of equity capital and expected returns is a function of beta and cash flow volatility, leverage, and growth. They conclude that studies employing implied cost of equity capital as a proxy for expected return should control for those factors. Thus, we control for the following:[26]

ubeta = coefficient from a single factor value-weighted market model measured during the last month of each quarter using the previous 60 months' returns including firms with at least 24 observations in that period, unlevered by dividing by (1 + long-term debt/market value of equity);

---

[24] We acknowledge the difficulty in identifying a reliable measure of the cost of equity capital, reflected in discussion in the literature about deficiencies in existing *ex ante* measures of the implied cost of equity capital (Easton and Monahan 2005; Guay et al. 2005; Botosan et al. 2010; Easton and Monahan 2010). These limitations apply to our study as well as to all other studies that examine accounting-based cost of capital measures.

[25] For example, Dhaliwal et al. (2007) control for factors suggested by Gebhardt et al. (2001), as well as Fama and French (1996) factors. Ogneva et al. (2007) and Ashbaugh-Skaife et al. (2009) also control for firm characteristics, such as mergers, percentage of losses, z-score decile, extent of foreign operations, and number of segments. To the extent data for these controls are available quarterly, we also estimated our models using the controls proposed by these referenced studies and found results consistent with those reported here.

[26] Because Hughes et al. (2009) did not specify empirical measures of constructs such as cash flow volatility and growth, we examined several alternative measures using, for example, free cash flow and return on equity. We also acknowledge these control variables likely do not fully correct for all problems with the underlying cost of capital measures. Use of these controls, however, should improve our analysis compared to other available sets of controls. To the degree these are related to use of SPVs, use of these controls should bias against our hypothesized results. Further, although we report results using the control variables defined here, the results are also robust to alternate sets of control variables including controls relating to performance, firm structure and governance, compensation effects, and information environment.

sd_ocf = standard deviation of operating cash flows over the previous five years including firms with at least three annual observations in that period, log transformed;[27]
sd_beta = standard deviation of the four beta values over the previous year for each firm, log transformed;
leverage = long-term debt divided by the market value of equity;
oi_growth = current quarterly operating income before depreciation and amortization divided by the previous quarter's value; and
size = market value of equity (in millions of dollars) at the end of the previous fiscal year, log transformed. Inclusion of this control is consistent with work such as Kothari et al. (2009) given the known relation between size and equity returns (Berk 1995).

Descriptive Statistics for Sample Firms Pre- and Post-FIN 46

Panel A of Table 2 presents descriptive statistics for the full sample of 1,389 firms for the pre-FIN 46 for three periods: (1) the pre-FIN 46 period, (2) the excluded time period (post-Enron scandal and during FIN 46 development), and (3) the post-FIN 46 period. We limited the sample to those firm-quarter observations with non-missing data for all variables. The mean (median) market capitalization ranges from $7.2 billion ($705 million) pre-FIN 46 to $6.7 billion ($1 billion) post-FIN 46. While leverage decreased over the 1998 through 2005 period, the average implied cost of equity capital (*re_ave*) likewise decreased from a mean value of 9.9 percent pre-FIN 46 to 9.0 percent post-FIN 46 consistent with Dhaliwal et al. (2007), who examined changes in implied cost of equity capital related to the Jobs and Growth Tax Relief Reconciliation Act of 2003.[28]

Tests Investigating Differences among Firm Categories

Panel B of Table 2 compares descriptive statistics for *F46* and *No_F46_Impact* firms. These groups have almost identical average implied cost of capital (*re_ave*), although *F46* firms have lower *re_peg* values and higher *re_ct* values. *F46* firms also have lower unlevered beta (*ubeta*), and lower cash flow volatility (*sd_ocf*) than the *No_F46_Impact* firms. *F46* firms are also generally larger and have higher leverage than *No_F46_Impact* firms. All measures taken together suggest that *F46* firms present lower risk profiles than the *No_F46_Impact* firms.

Figure 2 compares average implied cost of equity capital (*re_ave*) for the two groups of firms by quarter, adjusted for the mean quarterly cost of capital for all firms with available implied cost of equity capital measures. Thus, zero on the horizontal axis represents average implied cost of capital for all public firms for which implied cost of capital measures could be calculated each quarter. The lines indicate changes for *No_F46_Impact* and *F46* firms relative to a broad universe of firms. Clearly, *F46* firms have lower costs of equity capital pre-FIN 46; however, that advantage disappears by the end of 2001 and the *F46* firms have consistently higher average implied cost of equity capital values post-FIN 46.

Correlations among Implied Cost of Equity Capital Proxies and Other Risk Measures

Table 3 presents correlations among the cost of capital proxies and related control variables. As expected, the proxies for implied cost of equity capital are highly correlated. Those proxies are also significantly related to a variety of risk measures, consistent with prior research. The average cost of equity capital measure (*re_ave*) is significantly and negatively related to firm size and positively

---

[27] We added 1 to the standard deviation of cash flows and beta figures before log transformation.

[28] Although not shown in the table, interest rates on five-year and ten-year Treasury bonds also decreased from over 5 percent pre-FIN 46 to 4 percent or less post-FIN 46, reflecting economy-wide decreases in the cost of capital.

TABLE 2

Descriptive Statistics

Panel A: Descriptive Statistics by Period Pre- and Post-FIN 46 (n = 20,350 Firm-Quarter Observations)

(continued on next page)

related to leverage, consistent with Botosan and Plumlee (2005). It is also significantly and positively related to measures of operating cash flow and beta volatility (*sd_ocf* and *sd_beta*), consistent with Hughes et al.'s (2009) arguments that implied cost of equity capital is a function of beta and cash flow volatility, as well as leverage and growth. Similar to prior research, all the implied cost of capital measures, except *re_peg*, are negatively related to beta.

, * Indicate significance at 5 percent and 1 percent levels, respectively.

ns indicates not significant.

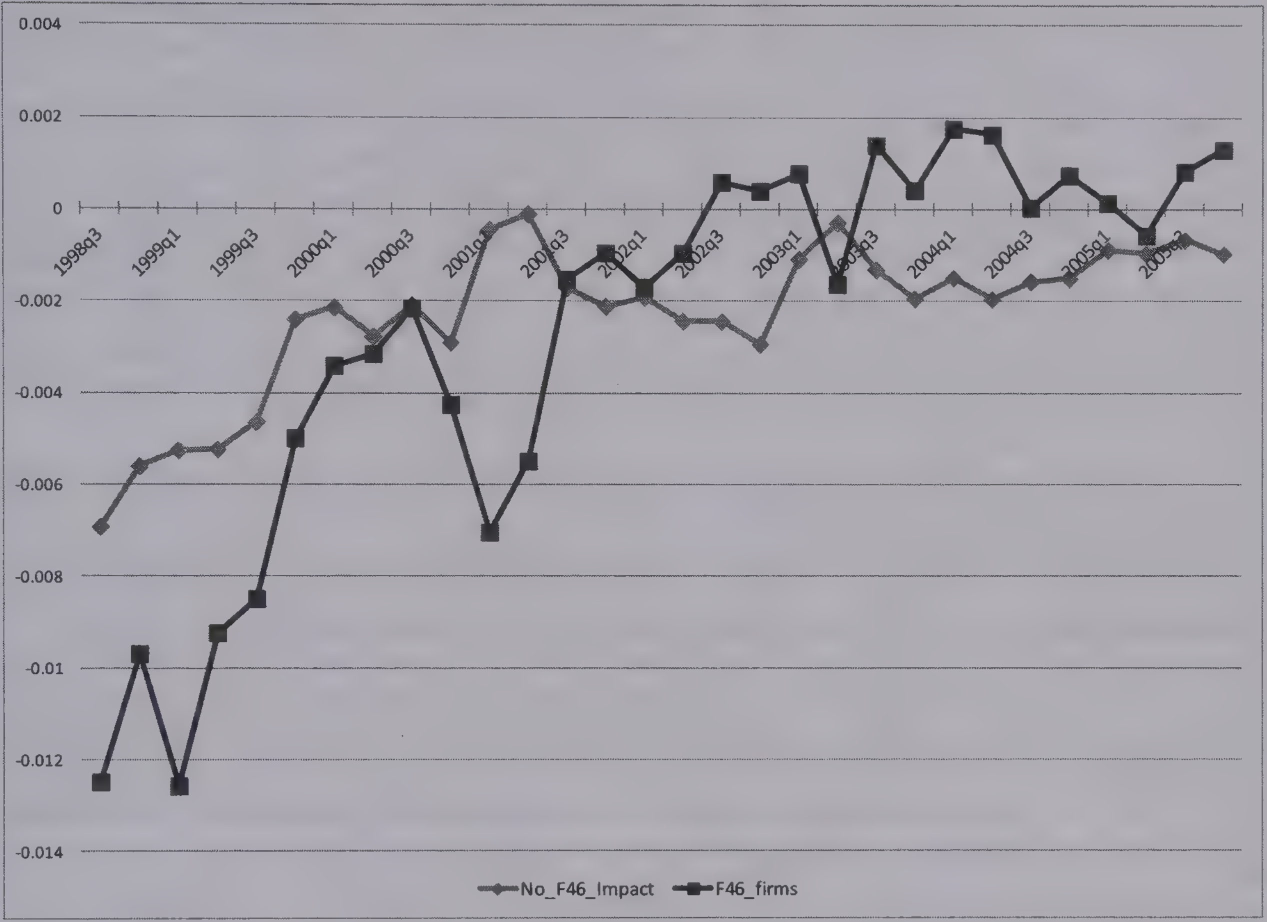
Panel A presents descriptive statistics for sample firms by period: (1) Pre-FIN 46 period is the 12 calendar quarters beginning with the 3rd quarter 1998 and ending with the 2nd quarter 2001, (2) the excluded period is the six quarters beginning with the 3rd quarter 2001 and ending with the 4th quarter 2002, and (3) the Post-FIN 46 period is the 12 quarters beginning with the 1st quarter 2003 and ending with the 4th quarter 2005. We limit the sample to those firm-quarter observations for which all the variables are available.

Panel B presents mean and median values for sample firms across all three time periods according to firm category: (1) *No_F46_Impact* firms are those firms that indicated that FIN 46 had no meaningful effect on their financial results, and (2) *F46 firms* are those firms that reported complying with FIN 46. The Comparison column indicates whether there is a significant difference between values for *No_F46_Impact firms* and *F46 firms* using two-tailed tests adjusting for intrafirm correlation with clustered standard errors.

Variable Definitions:

re_ave = average of other four measures of implied cost of capital;
re_ct = implied cost of capital based on Claus and Thomas (2001);
re_gls = implied cost of capital based on Gebhardt et al. (2001);
re_peg = implied cost of capital based on Easton (2004) PEG ratio;
re_oj = implied cost of capital based on Ohlson and Juettner-Nauroth (2005); *re* values are winsorized 1 percent at the high end of the distribution to limit the influence of extreme observations;
ubeta = unlevered beta, calculated by dividing beta by (1 + long-term debt/market value of equity); beta values are based on a single factor (value-weighted) market model based on monthly observations for firms with at least 30 observations in the previous 60 months;
sd_ocf = standard deviation of operating cash flows over previous five years plus 1, log transformed;
sd_beta = standard deviation of beta values over previous year plus 1, log transformed (proxy for beta volatility as suggested by results of Hughes et al. [2009]);
leverage = long-term debt divided by market value of equity, winsorized 1 percent at each end of the distribution;
oi_growth = operating income this quarter divided by operating income in the previous quarter, winsorized 1 percent at each end of the distribution; and
size = market value of equity ($mm) at the end of the previous fiscal year.

FIGURE 2
Quarterly Average Implied Cost of Capital (Mean-Adjusted) from 1998 to 2005 by Firm Category



This chart shows the average, quarterly mean-adjusted, implied cost of equity capital calculated quarterly over the period 1998 to 2005 for categories of firms defined as follows: (1) *No_F46_Impact* firms are those firms that indicated that FIN 46 had no meaningful effect on their financial results; and (2) *F46* firms are those firms that disclosed an effect from FIN 46. Quarterly mean values are based on all firms with available implied cost of equity capital measures for the quarter.

Models for Multivariate Tests of Implied Costs of Equity Changes Post-FIN 46 (H1)

To test H1, we examine the change in implied cost of equity capital post-FIN 46 for two different categories of firms: (1) the *No_F46_Impact* group with VIEs or SPVs not materially affected by FIN 46, and (2) the *F46* firms that complied with FIN 46, as described earlier, using the following basic model (firm and time subscripts suppressed):

$$re = b_0 + b_1 post46 + b_2 F46 + b_3 post46 \times F46 + b_4 ubeta + b_5 sd\_ocf + b_6 sd\_beta + b_7 leverage + b_8 oi\_growth + b_9 size + \varepsilon. \quad (1)$$

In Equation (1) *re* is one of the four implied cost of equity capital measures or the average measure and *post46* indicates the change in regime from pre- to post-FIN 46. The interaction term coefficient, b_3, indicates whether cost of capital changed for *F46* firms relative to *No_F46_Impact* firms, after controlling for other factors expected to affect cost of equity capital.

Table 3 presents Pearson correlations below the diagonal and Spearman correlations above the diagonal. Absolute correlations > 0.02 significant at 1 percent. n equals 14,563 firm-quarter observations. Variables are as defined in Table 2, except *size* is log transformed for this table.

Models for Multivariate Tests of Implied Costs of Equity Changes by VIE Action (H2)

To test H2, we divided *F46* firms into two subcategories based on the action they took in response to FIN 46: (1) *F46_on_books* firms brought VIE assets and liabilities onto the firm's balance sheet, and (2) *F46_off_books* firms kept VIE assets and liabilities off the firm's balance sheet.[29] We test changes in implied cost of equity capital using the following model where variables other than firm action categories are as previously defined:

$$\begin{aligned} re = {} & b_0 + b_1 post46 + b_2 F46\_off\_books + b_3 F46\_on\_books + b_4 post46 \times F46\_off\_books \\ & + b_5 post46 \times F46\_on\_books + b_6 ubeta + b_7 sd\_ocf + b_8 sd\_beta + b_9 leverage \\ & + b_{10} oi\_growth + b_{11} size + \varepsilon. \end{aligned} \tag{2}$$

Econometric Considerations

Our sample is an unbalanced panel of 1,389 firms over 24 quarters. Peterson (2009) compared alternative approaches for dealing with serial correlation in panel datasets and concluded that, in the presence of unobserved firm effects, clustered standard errors are unbiased and produce correctly sized confidence intervals while controlling for those unobserved effects. We therefore present results estimated using OLS with clustered standard errors adjusted for intrafirm correlation.[30]

Because firms chose their policies following FIN 46, self-selection bias may arise.[31] However, it is reasonable to assume that firms selected actions to minimize the adverse impact of FIN 46. Thus, firm choice should act to reduce the impact of FIN 46, counter to our hypotheses that FIN 46 affected the cost of equity capital.

---

[29] Some firms with multiple VIEs took both actions and we classified those firms as *F46_on_books* firms.

[30] We also analyze our models using the dual controls suggested by Gow et al. (2010) to account for cross-sectional and time-series dependency. While this method does cause small changes in the standard errors, it does not change the results reported in the following sections.

[31] Firms also chose to participate in off-balance sheet activities, but that choice should not affect post-FIN 46 cost of capital.

V. RESULTS

Results for Tests of Implied Cost of Equity Changes by Firm Category (H1)

Table 4 presents results comparing implied cost of equity capital pre- and post-FIN 46 by firm category. Panel A presents univariate tests of average implied cost of equity capital (*re_ave*) values for the pre- and post-FIN 46 periods. Both *F46* and *No_F46_Impact* firms experienced, on average, significantly lower cost of equity capital post-FIN 46 compared to pre-FIN 46. However, costs for *No_F46_Impact* firms decreased, on average, 1.1 percent, while *F46 firms* decreased only 0.6 percent and these differences are significantly different from one another ($p < 0.01$, one-tailed test). As shown in Figure 2, across adoption of FIN 46, cost of capital for *F46* firms changed from less than to greater than that of *No_F46_Impact* firms.

Panel B of Table 4 presents results from the multivariate analysis using Equation (1). The *post46* variable indicates the change in regime from pre- to post-FIN 46 and is significantly negative. The interaction term, *post46* × *F46* firms, then captures the post-FIN 46 change for *F46* firms relative to the *No_F46_Impact* firms. Focusing on results for the average implied cost of equity capital (*re_ave*), the coefficient on *post46* × *F46* is positive and highly significant ($p < 0.01$). Consistent with prior research (Botosan and Plumlee 2005), leverage is significant and positively related to *re_ave*, while *size* is significant and negatively related to *re_ave*, as well as to all of the other cost of equity capital proxies. Unlevered beta (*ubeta*) is significantly negatively related to *re_ave*. Among the control variables suggested by Hughes et al. (2009) and shown in Equation (1), only beta volatility (*sd_beta*) is not significantly related to *re_ave*, although it is significantly related to *re_gls*, *re_peg*, and *re_oj*. Overall, these results support H1. Cost of equity capital increased for firms with VIEs subject to FIN 46 relative to firms that reported no material effect from FIN 46.

Results for Tests of Implied Cost of Equity Changes by VIE Action (H2)

To examine the impact of actions taken to comply with FIN 46, we divided the *F46* firms into two categories according to whether they kept VIEs off (*F46_off_books*) or brought VIEs onto (*F46_on_books*) their books. Figure 3 shows that pre-FIN 46, the cost of equity capital moves together for those two groups; however, post-FIN 46, the average cost of equity capital diverges and *F46_on_books* firms have higher adjusted cost of equity capital than *F46_off_books* firms.

Panel A of Table 5 presents univariate results comparing the implied cost of equity capital pre- and post-FIN 46 for *No_F46_Impact*, *F46_off_books*, and *F46_on_books* firms. Both *No_F46_Impact* and *F46_off_books* firms experienced significant decreases in *re_ave* from pre- to post-FIN 46, but *F46_on_books* firms did not. Furthermore, the *F46_on_books* firms experienced a significantly smaller decrease than the *No_F46_Impact* firms ($p < 0.01$, one-tailed test) as well as the *F46_off_books* firms ($p < 0.05$, one-tailed test).

Panel B of Table 5 presents results from the multivariate analysis using Equation (2). Again, the *post46* variable indicates the change in regime from pre- to post-FIN 46 and is significantly negative. The interaction terms *post46* × *F46_off_books* and *post46* × *F46_on_books* reflect the relative post-FIN 46 change for those two firm categories. Focusing on results for the average implied cost of equity capital (*re_ave*), the *post46* × *F46_off_books* coefficient is not significant, but the *post46* × *F46_on_books* coefficient is positive and highly significant ($p < 0.01$). In untabulated tests the difference in coefficients between *post46* × *F46_on_books* and *post46* × *F46_off_books* is marginally significant ($p < 0.10$, F-test). The results for control variables are similar to those in Panel B of Table 4.[32]

---

[32] We also separately examine for each group the residuals (e.g., unexplained cost of equity) remaining after controlling for the Hughes et al. (2009) control variables; both univariate and multivariate analyses of these residuals are consistent with the results reported in Tables 4 and 5.

Robust standard errors adjusted for intrafirm correlation with clustered standard errors are in parentheses.

Panel A presents mean values for average implied cost of equity capital (*re_ave*) during the pre- and post-FIN 46 periods for firms reporting no material FIN 46 effect (*No_F46_Impact*), and for firms subject to FIN 46 (*F46*). The Prob(pre < > post) column indicates whether the change in *re_ave* is significantly different from zero, and the Prob(> *No_F46_Impact*) column indicates whether the change in *re_ave* was significantly greater than the change for *No_F46_Impact* firms (one-tailed test) correcting for intrafirm correlation with clustered standard errors.

(continued on next page)

TABLE 4 (continued)

Panel B presents OLS regressions testing H1 using the following model to compare firms' implied cost of capital between the pre-FIN 46 period (1998 Qtr 3 to 2001 Qtr 2) and the post-FIN 46 period (2003 Qtr 1 to 2005 Qtr 4), excluding observations from 2001 Qtr 3 to 2002 Qtr 4, according to whether the firm had VIEs and complied with FIN 46:

$$re = b_0 + b_1 post46 + b_2 F46 + b_3 post46 \times F46 + b_4 ubeta + b_5 sd\_ocf + b_6 sd\_beta + b_7 leverage + b_8 oi\_growth + b_9 size + \varepsilon.$$

Variable Definitions:
re = indicates one of the following accounting-based measures of implied cost of capital:
re_ave = average of other four measures of implied cost of capital;
re_ct = implied cost of capital based on Claus and Thomas (2001);
re_gls = implied cost of capital based on Gebhardt et al. (2001);
re_peg = implied cost of capital based on the Easton (2004) PEG ratio;
re_oj = implied cost of capital based on Ohlson and Juettner-Nauroth (2005);
re values are winsorized 1 percent at the high end of the distribution to limit the influence of extreme observations;
post46 = 1 if calendar quarter is during 2003 Qtr 1 to 2005 Qtr 4, 0 if calendar quarter is during 1998 Qtr 3 to 2001 Qtr 2;
F46 = 1 if firm reported complying with FIN 46, 0 otherwise;
post46 × *F46* = interaction term with value of 1 if both *post46* and *F46* firms equal 1, 0 otherwise;
ubeta = unlevered beta based on single factor market model;
sd_ocf = standard deviation of operating cash flows over previous five years plus 1, log transformed;
sd_beta = standard deviation of beta values over previous year plus 1, log transformed (proxy for beta volatility as suggested by Hughes et al. [2009]);
leverage = long-term debt divided by market value of equity, winsorized 1 percent at each end of the distribution;
oi_growth = operating income this quarter divided by operating income in previous quarter, winsorized 1 percent at each end of the distribution; and
size = log of market value of equity ($mm) at the end of the previous fiscal year.

Overall, Table 5 provides support for H2. The impact of FIN 46 on firms' cost of equity capital depends on the action that firms took to comply with FIN 46. Firms that reported consolidation of VIEs experienced the largest relative change in implied cost of equity capital post-FIN 46, an increase of approximately 70 basis points for the *re_ave* measure. In summary, the results show that FIN 46 affected *ex ante* measures of cost of equity capital for firms with VIEs impacted by FIN 46 relative to firms with no impact from the standard. Firms that consolidated VIEs (*F46_on_books* firms) following FIN 46 saw the largest relative increase in implied cost of equity capital. These results suggest that by restricting off-balance sheet options, the potential effect of FIN 46 on firms' future cash flows outweighed any benefit from more transparent disclosures.

Supplementary Analysis

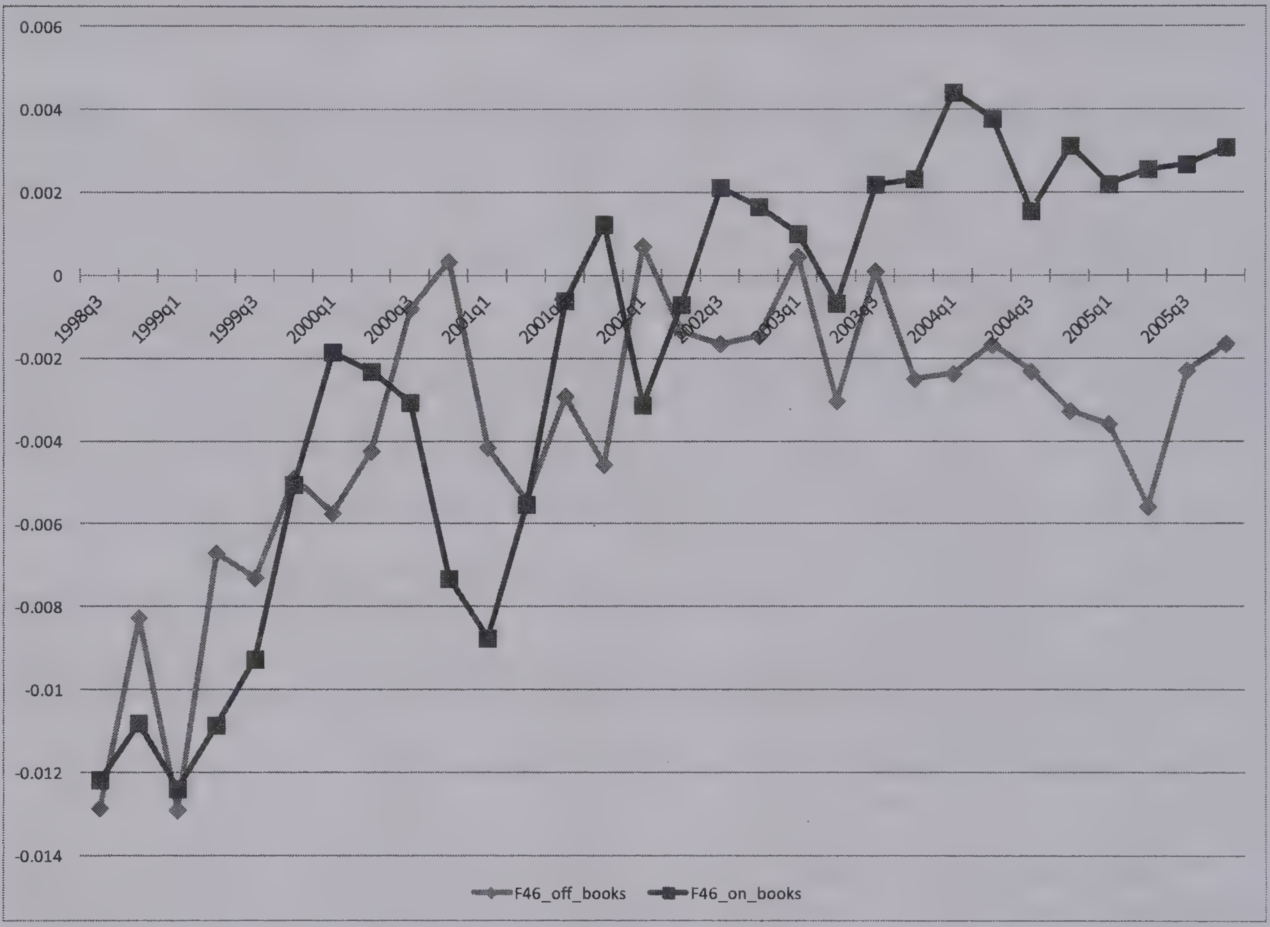
In untabulated analysis[33] consistent with the methodology in Table 5, we also considered whether different types of VIEs modify the effects documented here. First, we categorized *F46_on_books* VIEs as described in Panel B of Table 1 and performed univariate analysis of average implied cost of capital (*re_ave*) for *F46_on_books* firms by VIE type, compared to the *No_F46_Impact* and *F46_off_books* firms. Although multiple VIE firms had changes in *re_ave* similar to the *No_F46_Impact* firms, *F46_on_books* firms (categorized by VIE type) generally had significantly smaller decreases than firms not consolidating VIEs under the standard ($p < 0.05$). Next, in untabulated multivariate analysis we further examined the effect of VIE type on *re_ave*.

---

[33] The results discussed in this section are untabulated but are available upon request.

FIGURE 3

Quarterly Average Implied Cost of Capital (Mean-Adjusted) from 1998 to 2005 for FIN 46 Off-Books and On-Books Firms



This chart shows the average, quarterly mean-adjusted, implied cost of equity capital calculated quarterly over the period 1998 (quarter 3) to 2005 (quarter 4) for F46 firms according to the action taken with their VIEs post-FIN 46: keeping off books (*F46_off_books*) or bringing them onto books (*F46_on_books*). Quarterly mean values are based on all firms with available implied cost of equity capital measures for the quarter.

The *post46* interaction coefficients terms for both financial and other VIEs are significantly positive at the 1 percent level (coefficients of 0.013 and 0.025, respectively) and the other VIE interaction coefficient is the largest, but there are few firms in that group. Overall, these results suggest type of VIE does not materially affect the impact of FIN 46 on implied cost of capital.

We also examined an additional control sample of firms unaffected by FIN 46 (e.g., those firms making no disclosures about FIN 46 and reporting no likely SPVs within Exhibit 21). The majority of this sample of 2,296 firms (which we term *No_VIE* firms) did not file an Exhibit 21. These firms serve as an additional benchmark against which to evaluate our *F46* and *No_Impact_F46* groups. Across adoption of FIN 46, we found the decrease in *re_ave* for *No_VIE* firms to be significantly greater than the decrease for both *No_F46_Impact* and *F46* firms ($p < 0.01$, two-tailed test), and the decrease for *No_F46_Impact* firms was also significantly greater than that for *F46* firms ($p < 0.01$, two-tailed test). Untabulated multivariate analysis including this group yields stronger, but consistent results compared to those reported here.

Considering Botosan and Plumlee (2005), we also examined a cost of equity estimate based on Value Line forecasts ($r_{DIVPREM}$). This untabulated analysis finds very little difference across firm

TABLE 5

(continued on next page)

TABLE 5 (continued)

Panel A presents mean values for average implied cost of equity capital (*re_ave*) during the pre- and post-FIN 46 periods for firms reporting no material FIN 46 effect (*No_F46_Impact*) and for firms subject to FIN 46 (*F46* firms) subdivided according to whether the firms kept the VIEs off their books (*F46_off_books*) or brought the VIEs onto their books (*F46_on_books*). The Prob(pre < > post) column indicates whether the change in *re_ave* is significantly different from zero, the Prob(> *No_F46_Impact*) column indicates whether the change in *re_ave* was significantly greater than the change for *No_F46_Impact* firms (one-tailed test), and Prob(> *F46_off_books*) column indicates whether the change in *re_ave* for *F46_on_books* firms is significantly greater than the change for *F46_off_books* firms (one-tailed tests correcting for intrafirm correlation with clustered standard errors).

Panel B presents OLS regressions testing H2 using the following model to compare firms' implied cost of capital between the pre-FIN 46 period (1998 Qtr 3 to 2001 Qtr 2) and the post-FIN 46 period (2003 Qtr 1 to 2005 Qtr 4), excluding observations from 2001 Qtr 3 to 2002 Qtr 4, according to the action taken by the firm with respect to the reported VIEs:

$$\begin{aligned} re = {} & b_0 + b_1 post46 + b_2 F46\_off\_books + b_3 F46\_on\_books + b_4 post46 \times F46\_off\_books \\ & + b_5 post46 \times F46\_on\_books + b_6 ubeta + b_7 sd\_ocf + b_8 sd\_beta + b_9 leverage + b_{10} oi\_growth + b_{11} size + \varepsilon. \end{aligned}$$

Variable Definitions:
re = indicates one of the following three accounting-based measures of implied cost of capital:
re_ave = average of other four measures of implied cost of capital;
re_ct = implied cost of capital based on Claus and Thomas (2001);
re_gls = implied cost of capital based on Gebhardt et al. (2001);
re_peg = implied cost of capital based on the Easton (2004) PEG ratio;
re_oj = implied cost of capital based on Ohlson and Juettner-Nauroth (2005);
re values are winsorized 1 percent at the high end of the distribution to limit the influence of extreme observations;
post46 = 1 if calendar quarter is during 2003 Qtr 1 to 2005 Qtr 4, 0 if calendar quarter is during 1998 Qtr 3 to 2001 Qtr 2;
F46_off_books = 1 if firm reported complying with FIN 46 but kept VIEs off their books, 0 otherwise;
F46_on_books = 1 if firms reported complying with FIN 46 and consolidated or otherwise brought the VIEs onto their books, 0 otherwise;
post46 × *F46_off_books* = interaction term;
post46 × *F46_on_books* = interaction term;
ubeta = unlevered beta based on single factor market model, winsorized 1 percent at each end of the distribution;
sd_ocf = standard deviation of operating cash flows over previous five years, log transformed;
sd_beta = standard deviation of beta values over previous year (proxy for beta volatility as suggested by results of Hughes et al. [2009]);
leverage = long-term debt divided by market value of equity, winsorized 1 percent at each end of the distribution;
oi_growth = operating income this quarter divided by operating income in previous quarter, winsorized 1 percent at each end of the distribution; and
size = log of market value of equity ($ mm) at the end of the previous fiscal year.

type. However, Value Line documentation indicates that Value Line forecasts after 2003 are largely based on pre-FIN 46 data and, therefore, the $r_{DIVPREM}$ measure would reflect only changes due to FIN 46, if any, with substantial delay.[34]

Additionally, we considered whether the impact of FIN 46 on debt ratios affected firms' cost of equity capital. We formed three portfolios for *F46* firms based on debt ratios prior to FIN 46 and additional liabilities recorded due to consolidating VIEs. In untabulated results we found that firms with high debt ratios and the highest increase in liabilities from VIEs experienced a 220 basis point increase in average cost of equity capital (*re_ave*). This change was significantly greater than for firms in the other two categories, both of which experienced changes similar to the *No_F46_Impact* firms. Firms in the high debt category also had the lowest relative cost of equity capital pre-FIN 46.

---

[34] Specifically, the documentation says, "The 3–5 year average price is determined by applying a 'normalized' P/E ratio to projected 3–5 year earnings per share." Value Line estimates their EPS growth from the recent average growth rate ("The annual compounded growth rate using the average of the three latest base years.").

Finally, consistent with previously discussed theory and evidence, we also examined changes in cost of debt surrounding adoption of FIN 46. In untabulated multivariate analysis of credit ratings using Compustat S&P ratings and controls previously established in the literature (e.g., Jorion et al. 2005; Jiang 2008), we find long-term issuer credit ratings did not significantly change after FIN 46, although we observe more downgrades for firms associated with VIEs.[35] Further, the results suggest *F46_on_books* firms had better credit ratings prior to FIN 46 than did *No_F46_Impact* and *F46_off_books* firms. Credit ratings in general deteriorated after FIN 46, significantly so for the *No_F46_Impact* and *F46_on_books* firms; however, in the multivariate analysis, we did not observe significant increases in cost of debt for either *F46_off_books* or *F46_on_books* firms.

VI. CONCLUSIONS

This study explores whether adoption of FASB Interpretation No. 46/R (FIN 46), *Consolidation of Variable Interest Entities—An Interpretation of ARB No. 51*, in 2003 changes the cost of equity capital for affected firms. Using comparative analysis on a broad sample of 11,719 firm-quarter observations for 1,389 firms during the period 1998 to 2005, we find evidence that FIN 46 significantly increased the cost of equity capital for firms with affected VIEs by an average of 50 basis points. Further, firms that consolidated these formerly off-balance sheet structures experienced the largest increase. Additional analysis finds that the type of VIE does not materially affect the impact of FIN 46 on implied cost of equity capital. Further, the cost of debt as proxied by debt credit ratings did not significantly change after FIN 46, although debt downgrades increased.

Consistent with warnings from some financial analysts that the changes initiated by FIN 46 could adversely affect loan covenants, credit ratings, and regulatory capital requirements, our results indicate firms with VIE structures were, in general, negatively affected by FIN 46. Taken together, these results suggest FIN 46 reduced the opportunity for firms to use off-balance sheet structures to reduce their cost of equity capital. Our findings imply the FASB's stated purpose in enacting FIN 46 was at least partially satisfied.

This study is subject to limitations. We tested the cost of capital implications of FIN 46 using a variety of *ex ante* measures of cost of equity capital, all widely used in prior research. We compared values for individual, as well as the average, *ex ante* measures of implied cost of equity capital for a three-year period pre-FIN 46 against a similar period post-FIN 46 for firms materially impacted by FIN 46 against those that were not. We recognize the ongoing debate about the validity of implied cost of equity capital measures, but our use of these measures is consistent with current academic literature and appropriate for understanding the impact of FIN 46, given the theoretical asset-pricing literature to date.

APPENDIX A

Exhibit 1: On-Books Financial VIE—Black Hills Corp (12/31/2003)

FIN 46-R

In January 2003, the FASB issued Interpretation No. 46, *Consolidation of Variable Interest Entities* (FIN 46). In December 2003, the FASB issued FIN No. 46 (Revised) (FIN 46-R) to address certain FIN 46 implementation issues. The Company's subsidiary, Black Hills Wyoming, has an agreement with Wygen Funding, Limited Partnership, an unrelated variable interest entity (VIE) to lease the Wygen plant. Under the new accounting interpretation, as amended, the Company consolidated the VIE effective December 31, 2003. The effect of consolidating the VIE into the Company's Consolidated Balance Sheet was an increase in total assets of $129.0 million, of which $121.5 million, net of accumulated depreciation of $3.0 million, is included in Property, Plant, and Equipment and an increase in long-term debt in the amount of $128.3 million. Prior to the December 31, 2003 consolidation, the Company recorded lease expense on the Wygen plant. Lease payments began upon completion of the plant in February 2003. During 2003, lease payments were $2.7 million and are included in Operations and Maintenance on the accompanying 2003 Consolidated Statement of Income. The net effect of consolidating the income statement of the VIE on December 31, 2003 was to recognize a cumulative effect charge for $2.5 million (net of $1.4 million of income taxes), which represents the depreciation and interest expense that would have been recorded had the VIE been consolidated at inception. The net effect on future results will be to recognize depreciation and interest expense in place of recognizing lease expense, which is estimated to have an approximate $3.0 million negative annual effect to after-tax net income.

Exhibit 2: On-Books Operational VIE—Cisco Systems, Inc. (07/31/2004)

Acquisition of Andiamo Systems, Inc.

In April 2001, the Company entered into a commitment to provide convertible debt funding of approximately $84 million to Andiamo, a privately held storage switch developer. This debt was convertible into approximately 44 percent of the equity of Andiamo. In connection with this investment, the Company obtained a call option that provided the Company the right to purchase Andiamo. The purchase price under the call option was based on a valuation of Andiamo using a negotiated formula. On August 19, 2002, the Company entered into a definitive agreement to acquire Andiamo, which represented the exercise of its rights under the call option. The Company also entered into a commitment to provide nonconvertible debt funding to Andiamo of approximately $100 million through the close of the acquisition. Substantially all of the convertible debt funding of $84 million and nonconvertible debt funding of $100 million has been expensed as research and development costs.

The Company adopted FIN 46(R) effective January 24, 2004. The Company evaluated its debt investment in Andiamo and determined that Andiamo was a variable interest entity under FIN 46(R). The Company concluded that the Company was the primary beneficiary as defined by FIN 46(R) and, therefore, accounted for Andiamo as if the Company had consolidated Andiamo since the Company's initial investment in April 2001. The consolidation of Andiamo from the date of the Company's initial investment required accounting for the call option as a repurchase right. Under FASB Interpretation No. 44, *Accounting for Certain Transactions Involving Stock Compensation*, and related interpretations, variable accounting was required for substantially all Andiamo employee stock and options because the ending purchase price was primarily derived from a revenue-based formula.

Effective January 24, 2004, the last day of the second quarter of fiscal 2004, the Company recorded a noncash cumulative stock compensation charge of $567 million, net of tax (representing the amount of variable compensation from April 2001 through January 2004). This charge was reported as a separate line item in the Consolidated Statements of Operations as a cumulative effect of accounting change, net of tax. The charge was based on the value of the Andiamo employee stock and options and their vesting from the adoption of FIN 46(R) pursuant to the formula-based valuation.

On February 19, 2004, the Company completed the acquisition of Andiamo, exchanging approximately 23 million shares of the Company's common stock for Andiamo shares not owned by the Company and assuming approximately 6 million stock options, for a total estimated value of $750 million, primarily derived from the revenue-based formula, which after stock-price-related adjustments resulted in a total amount recorded of $722 million, as summarized in the table below.

Subsequent to the adoption of FIN 46(R), changes to the value of Andiamo and the continued vesting of the employee stock and options resulted in an adjustment to the noncash stock compensation charge. The Company recorded a noncash variable stock compensation adjustment of $58 million in the third quarter of fiscal 2004 to the cumulative stock compensation charge recorded in the second quarter of fiscal 2004 to account for the additional vesting of the Andiamo employee stock and options and changes in the formula-based valuation from January 24, 2004 until February 19, 2004. This noncash adjustment was reported as operating expense in the Consolidated Statements of Operations, as amortization of deferred stock-based compensation in the Consolidated Statements of Cash Flows, and as an increase to additional paid-in capital in the Consolidated Statements of Shareholders' Equity. In addition, upon completion of the acquisition, deferred stock-based compensation of $90 million was recorded in the Consolidated Balance Sheets to reflect the unvested portion of the formula-based valuation of the Andiamo employee stock and options. The amount of deferred stock-based compensation was fixed at the date of acquisition and will be amortized over the remaining vesting period of Andiamo employee stock and options of approximately two years.

A summary of the accounting of the consolidation under FIN 46(R) and the subsequent purchase of Andiamo, after stock price related adjustments, is as follows (in millions):

	Amount
Cumulative effect of accounting change, net of tax benefit of	$567
Variable stock-based compensation	58
Deferred stock-based compensation	90
Net assets	7
Total	$722

Exhibit 3: Both On-Books and Off-Books Other VIE—Aetna, Inc. (12/31/2003)

Accounting for Variable Interest Entities ("VIE")

In January 2003, the FASB issued Interpretation No. 46, *Consolidation of Variable Interest Entities* (FIN 46). This interpretation requires the Company to consolidate a VIE if the entity meets certain criteria and the Company is considered the primary beneficiary of the VIE (such as where the Company has a direct or indirect ability to make significant decisions for the entity or the obligation to absorb a majority of the entity's expected losses or gains). FIN 46 also requires additional disclosure of the Company's relationship with a VIE regardless of whether the Company is the primary beneficiary.

In December 2003, the FASB issued a revision to Interpretation No. 46, *Consolidation of Variable Interest Entities* (FIN 46-R). FIN 46-R amended certain provisions of FIN 46 and delayed implementation for entities that are not considered special purpose entities until the first quarter of 2004. As of December 31, 2003, the Company has no investments that are considered special purpose entities.

The Company does not have any material relationships with VIEs that would require consolidation. The Company does have relationships with certain real estate partnerships that are considered VIEs. However, the Company would not be considered the primary beneficiary. The Company records the amount of its investment in these partnerships as an asset on its Consolidated Balance Sheet and recognizes its share of partnership income or losses in earnings. The Company's maximum exposure to loss as a result of its investment in these partnerships is its investment balance at December 31, 2003 of approximately $125 million and the risk of recapture of tax credits previously recognized, which the Company does not believe is significant. The partnerships construct, own, and manage low-income housing developments and had total assets of approximately $1.3 billion as of December 31, 2003.

Effective September 15, 2003, the Company's leasing program with an independent third party grantor trust (primarily for the lease of a corporate aircraft and certain office furniture), accounted for as an operating lease under previous accounting standards, was terminated, and the Company purchased those assets for cash. The Company would have been required to consolidate this grantor trust in accordance with the requirements of FIN 46.

APPENDIX B

Easton (2004) *re_peg* Measure

Easton (2004) develops a proxy for the cost of equity capital implied by the price-earnings-growth ratio (*re_peg*):

$$re\_peg = sqrt((eps_2 - eps_1)/price_0). \tag{1}$$

In Equation (1) eps_1 and eps_2 are the last mean earnings per share forecasts in the calendar quarter for fiscal years $t+1$ and $t+2$, respectively, and $price_0$ equals the market price at the end of the calendar quarter. The *re_peg* measure requires earnings growth to be positive. For the *re_peg* measure, we follow Francis et al. (2005a) and Botosan and Plumlee (2005) in assuming zero dividends per share.[36]

---

[36] We also calculated a version of the *re_peg* measure including dividends and found similar results in all analyses.

Ohlson and Juettner-Nauroth (2005) *re_oj* Measure

Our second proxy for the cost of equity capital was developed by Ohlson and Juettner-Nauroth (2005) and examined by Gode and Mohanram (2003):

$$re\_oj = A + sqrt(A^2 + (eps_1/price_0)(g_2 - (\gamma - 1)). \tag{2}$$

Again, eps_1 equals analyst forecasts of earnings per share for the following fiscal year, $price_0$ is the final price for the current calendar quarter, g_2 is the earnings growth percentage $((eps_2 - eps_1)/eps_1)$, and $\gamma{-}1$ is long-term growth rate set to the risk-free rate less 3 percent (Hribar and Jenkins 2004), and A equals:

$$A = \left(\frac{1}{2}\right)((\gamma - 1) + dps_1/price_0), \tag{3}$$

where dps_1 is the dividends per share for the following year assumed to continue at the same level as in the current year. We use ten-year U.S. Treasury bond rates as the risk-free rate (e.g., Hribar and Jenkins 2004; Dhaliwal et al. 2005). The long-term growth rate, $\gamma{-}1$, sets a lower bound on the *re_oj* measure.

Gebhardt et al. (2001) *re_gls* Measure

Our third cost of equity capital measure is based on Gebhardt et al. (2001). They use a version of the residual income valuation model (Ohlson 1995; Feltham and Ohlson 1995) to derive their proxy for the cost of equity capital:

$$P_t = B_t + \frac{FROE_{t+1} - r_e}{(1 + r_e)} B_t + \frac{FROE_{t+2} - r_e}{(1 + r_e)^2} B_{t+1} + TV, \tag{4}$$

where P_t equals the market price at the end of calendar quarter, B_t equals the book value per share at the beginning of the quarter, r_e equals the cost of equity capital, *FROE* equals the forecasted return on equity (forecasted eps_{t+i}/B_{t+i-1} for the $t{+}i$ period), and *TV* is a terminal value estimate calculated as follows:

$$TV = \sum_{i=3}^{T-1} \frac{FROE_{t+i} - r_e}{(1 + r_e)^i} B_{t+i-1} + \frac{FROE_{t+T} - r_e}{(1 + r_e)^{T-1}} B_{t+T-1}. \tag{5}$$

In Equations (4) and (5), we calculate $FROE_{t+3}$ by multiplying forecast eps_{t+2} by 1 plus the I/B/E/S long-term growth rate forecast.[37] We set $T = 12$ in Equation (5) and calculated the terminal value assuming that *ROE* linearly reverts to the industry median *ROE* over periods 4 to 12.[38] We calculate the industry median ROE using ten-year averages for Fama and French's (1997) 48 industry classifications, excluding loss firms from the calculation (Dhaliwal et al. 2005).[39] Assuming clean surplus accounting, we calculate $B_{t+1} = B_{t+1-1} + (1 - payout\ ratio) \times eps_{t+1}$, where *payout ratio* equals current dividends per share divided by current earnings per share.[40] In cases where the earnings per share are negative, we calculate the payout ratio as current dividends divided by 6 percent of total assets (Hribar and Jenkins 2004; Dhaliwal et al. 2005, 2007).[41]

---

[37] We constrained the maximum long-term growth rate to less than or equal to 50 percent, since long-term growth rates exceeding 50 percent are highly unlikely.

[38] We winsorized future *ROE* values at 1 percent on the high end of the distribution to limit the influence of untenable rates for forecast return on equity and also constrained *ROE* to be greater than zero.

[39] We also estimated *re_gls* values without removing loss firms from the calculation. The implied cost of equity capital measures was lower on average but the overall results were unaffected.

[40] We constrained the payout ratio to less than or equal to 1.

Claus and Thomas (2001) *re_ct* Measure

Claus and Thomas (2001) base their cost of equity capital measure on an alternate form of the residual income valuation model. In particular, they assume that abnormal earnings grow at a constant rate beyond the fifth year, in contrast to reverting to the industry median for the *re_gls* measure:

$$P_t = B_t + \frac{AE_{t+1}}{(1+r_e)} + \frac{AE_{t+2}}{(1+r_e)^2} + \frac{AE_{t+3}}{(1+r_e)^3} + \frac{AE_{t+4}}{(1+r_e)^4} + \frac{AE_{t+5}}{(1+r_e)^5} + \frac{AE_{t+5}(1+g_{ae})}{(r_e - g_{ae})(1+r_e)^5}, \tag{7}$$

where AE_{t+1} equals expected abnormal earnings for year $t+i$ calculated as forecasted $eps_{t+1} - r_e(B_{t+i-1})$, and g_{ae} is the growth rate on abnormal earnings equal to the yield on ten-year Treasury bonds (Hribar and Jenkins 2004; Dhaliwal et al. 2005, 2007). We estimate AE_{t+3} to AE_{t+5} by multiplying the prior-year forecast by the long-term growth forecast.[42] Again, we estimate B_{t+i} assuming clean surplus accounting and constant payout ratios as with the *re_gls* measure.[43]

---

[41] We calculated the implied cost of capital iteratively beginning with a value for *re* of 0.0001 and incrementing that value by 0.0001 until the calculated price is within 1 percent of the actual price. See Guay et al. (2005) for issues with respect to selecting the appropriate market price and adjusting the price for changes in shares outstanding.

[42] Again, where an I/B/E/S long-term growth rate was not available, we used $(eps_2 - eps_1)/eps_1$, and we constrained the maximum long-term growth rate to less than or equal to 50 percent, since long-term growth rates exceeding 50 percent are highly unlikely. I/B/E/S long-term growth rate estimates are not available for approximately 10 percent of the sample.

[43] For both the *re_gls* and *re_ct* measures, we calculate the implied cost of capital iteratively beginning with a value of 0.0001 and incrementing that value by 0.0001 until the calculated price is within 1 percent of the actual price. For the *re_ct* measure, the long-term growth in abnormal earnings, g_{ae}, presents a lower bound on the cost of equity capital.

Lost in Translation: The Effects of Incentive Compensation on Strategy Surrogation

Jongwoon (Willie) Choi

ABSTRACT: To facilitate managers' decision-making, firms develop strategic performance measurement systems that translate strategy into performance measures. Ideally, managers see measures for what they are—imperfect proxies for intangible strategic constructs. However, managers may fail to fully appreciate the fact that measures are merely representations of the strategic constructs, and act as though the measures are the construct of interest—a phenomenon we label *surrogation*. In this paper, we investigate whether and how the use of strategically linked performance measures for compensation purposes affects managers' propensity to exhibit surrogation. In accordance with the attribute substitution framework (Kahneman and Frederick 2002), we predict incentive compensation exacerbates surrogation, and that this effect is more prevalent when managers are compensated on a single measure of a strategic construct than when managers are compensated on multiple measures of a strategic construct. Via two experiments, we find support for these hypotheses. Our paper contributes to the literature on strategic performance measurement systems by highlighting the tendency of managers to use measures as surrogates for strategy. More

I. INTRODUCTION

Strategic performance measurement systems facilitate managers' decision-making by translating strategy into performance measures. A critical feature of these measurement systems is that the strategically linked performance measures be transparent (Kaplan and Norton 1996), allowing managers to "see through" the measures back to the strategy. This transparency allows managers to infer the firm's desired course of action, gauge the appropriateness of the strategy, and adjust the strategy as deemed necessary. Ideally, managers see measures for what they are—imperfect proxies for intangible, over-arching strategic constructs. However, managers may fail to fully appreciate the fact that measures are merely representations of the true constructs of interest, ultimately acting as if the imperfect measures *are* the constructs of interest. This behavior—which we label *surrogation*—potentially hinders managers' ability to make appropriate strategy-related judgments and decisions. The purpose of this paper is to investigate managers' propensity to exhibit surrogation when using a strategic performance measurement system.

Surrogation occurs in a wide variety of circumstances. For example, university administrators accustomed to focusing on teaching evaluations during faculty reviews may lose sight of the strategic construct of "teaching effectiveness" and behave as though the evaluations are the construct of interest (Brickley and Zimmerman 2001; Flinn and Crumbley 2009). Similarly, a manager charged with "delighting the customer" when customer satisfaction surveys gauge strategic success may begin to see maximizing survey results as the strategy, and behave accordingly (Grizzle 2002). In a market setting, investors may use a firm's financial statements repeatedly, and in the process lose sight of the construct(s) of interest that these statements represent (Ijiri 1967, 1975).

Under some circumstances, the phenomenon of surrogation is likely to be less important. For instance, losing sight of strategic constructs that underlie performance measures may be acceptable for low-level employees who do not make strategic judgments and decisions. Additionally, the phenomenon of surrogation is moot when contracts are complete or when measures perfectly capture underlying constructs. However, complete contracts are rarely seen in practice (Williamson 1985), and firms often make trade-offs between contract *completeness* and contract *complexity*. This occurs because managers often face settings in which constructs are intangible, ill-defined, and complex, necessitating the use of imperfect measures of the constructs as part of a firm's strategic performance measurement system.

Many factors are likely to influence managers' propensity toward surrogation. This study focuses specifically on the use of measures as a basis of compensation. Specifically, we ask whether tying incentive compensation to one or more performance measures affects managers' propensity to use measures as surrogates for strategic constructs.

We rely on literature in psychology to develop our theory. In particular, we leverage Kahneman and Frederick's (2002) notion of attribute substitution, which occurs when an individual has a judgment to make regarding a complex "target attribute," and instead relies on a more easily accessible "heuristic attribute" in their judgment process. Using this framework, we develop two hypotheses regarding the influence of incentive compensation on a manager's surrogation of strategy. Our first hypothesis predicts that basing a portion of a manager's compensation on a single measure of a strategic construct exacerbates surrogation of that construct, relative to when the manager receives a fixed wage. Specifically, we argue that the incentive compensation directs a manager's focus toward the compensated measure as a means of achieving higher compensation. Such attention-directing effects increase the accessibility of the compensated measure as a potential substitute for the construct of interest, increasing the likelihood that surrogation occurs, relative to when fixed-wage-compensation is used. Our second hypothesis predicts that incentive compensation based on multiple measures of a single strategic construct leads to less surrogation of that construct relative to when compensation is based on a single measure of that construct. In particular, we posit that managers are more likely to consider any single measure's capacity to represent the strategic construct when compensated on multiple measures of a strategic construct rather than on a single measure of that construct. Such consideration highlights the limitations of any one measure as a representation of the strategic construct, and according to attribute substitution theory, decreases the likelihood that managers use imperfect proxies as surrogates for the higher-level construct.

Investigating the effect of compensation on surrogation using archival or field data is challenging because of the difficulty of distinguishing surrogation from wealth-maximizing behavior. For example, a salesperson whose compensation is based on customer satisfaction survey scores may focus on maximizing customer satisfaction surveys both because the salesperson responds to incentives to maximize wealth *and* also because of surrogation whereby they view survey results as the strategic construct of interest. Determining where wealth maximization ends and where surrogation begins in such field settings is generally not possible. Therefore, we use an experiment to distinguish between surrogation and wealth maximization. To strengthen the test of our theory and hypotheses, we investigate our research question in a setting that, by necessity, does not map perfectly into the real-world settings in which we are most interested. This approach is similar to prior experimental work in accounting (Libby and Tan 1999; Tayler and Bloomfield 2011). Specifically, participants in our main experiment earn incentive compensation in one task, then move to a separate, similar task where incentive compensation is absent, allowing us to measure surrogation in isolation. In a follow-up experiment, we again induce surrogation via compensation manipulations in one task and measure surrogation in a separate task. However, in the second experiment we also provide compensation in the second task to help address alternative explanations for our results.

In the first task in our experiments, graduate business student participants in our study use the computer game *Spore* (Electronic Arts 2008; Lawton 2008) to design a virtual creature following a specified strategy. We provide four measures of a single strategic construct to participants in real-time as they design their creatures. We manipulate compensation tied to these measures at three levels: fixed-wage-compensation, incentive compensation based on a *single* measure of the creature's abilities, and incentive compensation based on *multiple* (three of the four) measures of the creature's abilities. After designing their creature, participants move to the next task where we measure their tendency to use measures as surrogates for the strategic construct. Each participant views a series of 18 virtual creatures and makes choices regarding the design of these creatures. We designed these choices to allow us to evaluate the extent to which incentive compensation influences participants' tendency to use compensated measures in the first task as surrogates for the strategy in the second task. Importantly, our main experiment does not tie these 18 design choices to compensation in any way, allowing us to view behavior absent the influence of incentive compensation. Based on these choices, we compute participants' "surrogation score," our key dependent variable.

We find evidence consistent with our hypotheses across both of our experiments. Participants compensated on a single measure of a strategic construct were more likely to exhibit strategy surrogation than participants who received a fixed wage. We observe this result even when participants had to incur an opportunity cost to make a choice reflecting surrogation. Further, we find evidence that participants compensated on multiple measures of a strategic construct were less likely to exhibit surrogation than participants compensated on a single measure of a strategic construct.

Our study contributes to the literature on strategic performance measurement systems by highlighting the tendency of managers to use measures as surrogates for strategy. While prior research identifies the potential for such behavior to arise (Ijiri 1967, 1975), little evidence exists to help explain *why* managers use performance measures as surrogates for strategic constructs. Not only do we provide a theory-based explanation for such behavior, but also we document how an important factor—the number of measures on which managers are compensated—affects surrogation. We also contribute to literature relating to the adage "you get what you measure" (Kerr 1975; Goldratt 2004) and the concept of "performance measure myopia" (Lambert 2001, 38), providing evidence relating to why individuals may engage in such behavior even when they have no direct financial incentive to do so. More generally, we identify a by-product of contracting on imperfect performance measures not previously considered in extant literature (Bushman and Indjejikian 1993; Feltham and Xie 1994; Budde 2007), and establish when consideration of costs of this by-product are likely to be critical.

The remainder of this paper proceeds as follows. Section II provides the background and hypotheses. Section III describes our experiment and related procedures. Section IV presents results. Section V concludes.

II. BACKGROUND AND HYPOTHESES

Strategic Performance Measurement Systems

A fundamental purpose of accounting is to provide a means by which decision-makers can grapple with abstract and complex constructs of interest (Ijiri 1967, 1975). Ideally, decision-makers could work directly with these constructs. However, given the nature of these constructs, accounting measures are useful media through which managers make decisions related to the constructs.

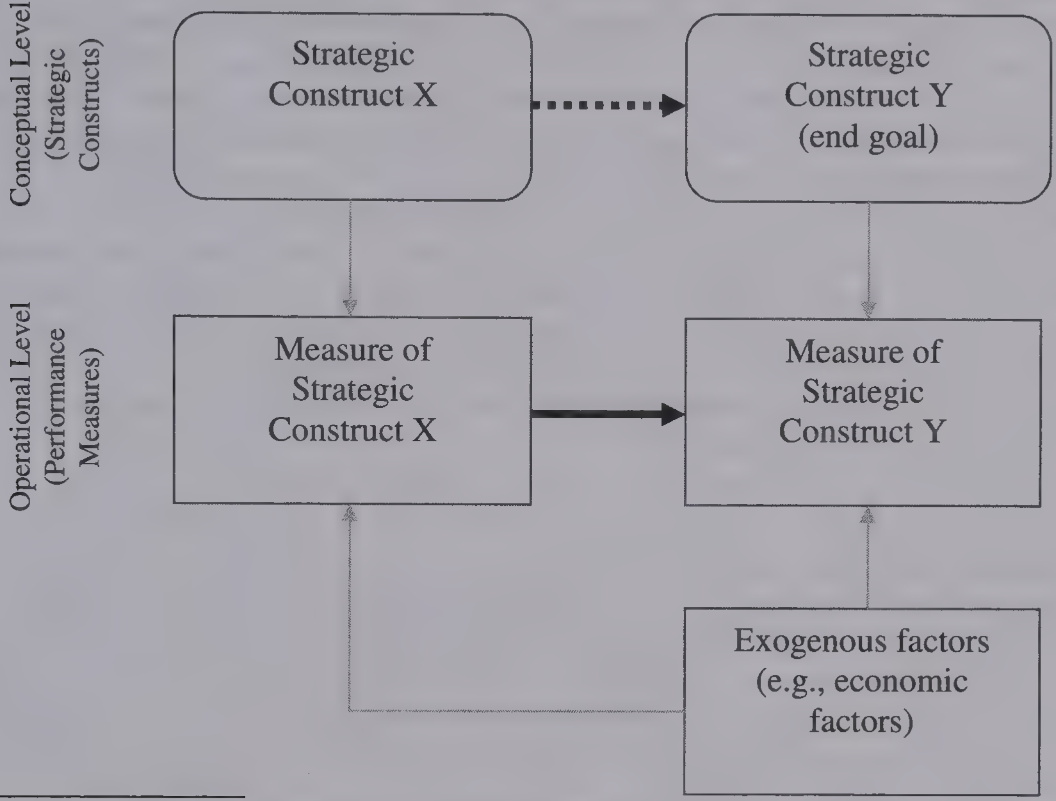
This fundamental purpose of accounting is embodied in the context of firms' strategic performance measurement systems. Prior research uses various labels for strategic performance measurement systems, including performance measurement models (Malina et al. 2007) and balanced scorecards (Kaplan and Norton 1992). In this paper, we refer to any system with an explicit link between strategy and performance measurement as a strategic performance measurement system (Epstein and Manzoni 1997; Webb 2004). A key feature of these systems is the mapping of relationships among strategic constructs and performance measures. These outlines are commonly referred to as strategy maps (Kaplan and Norton 2000), value driver maps (Ittner and Larcker 2003), or causal chains of performance (Tayler 2010) (see Figure 1).[1]

Prior research highlights the importance of linking firm strategy and performance measures, noting at least three key functions of such alignment (Langfield-Smith 1997; Ittner and Larcker 1998, 2001; Chenhall 2003). First, translating strategy into a set of measures facilitates *communication* of strategy throughout the firm (Malina and Selto 2001, 2004). That is, performance measures signal to managers potential actions to take, and inform them of how their actions affect others within the firm, as well as the firm as a whole. Second, aligning strategy with performance measures enables *evaluation* of strategy. Performance measures provide tangible evidence that managers use to determine the extent to which the firm is accomplishing its strategy (Bromwich 1990), and to test and validate the strategy (Campbell et al. 2008). Third, tying measures to strategy facilitates the *development* of new strategies (Simons 1991, 1994). Performance measure information can help managers to discover new strategic constructs and/or new strategies. Key to these functions is the transparency of measures, which allows managers to "see through" the measures back to the strategy (Kaplan and Norton 1996).

---

[1] Strategic constructs, which define the purpose of actions taken, are often referred to as strategic objectives (Kaplan and Norton 1996). A collection of causally connected strategic constructs define the strategy for an organization.

FIGURE 1
Linking Strategy to Measures of Performance



Conceptual Level (Strategic Constructs)
Operational Level (Performance Measures)
Strategic Construct X
Strategic Construct Y (end goal)
Measure of Strategic Construct X
Measure of Strategic Construct Y
Exogenous factors (e.g., economic factors)

Strategic performance measurement systems facilitate managers' actions by mapping relationships among strategic constructs and performance measures. Above is a simplified example of this mapping based, in part, on the predictive validity framework (Runkel and McGrath 1972; Libby 1981). Horizontal linkages at the *Conceptual Level* represent the hypothesized cause-and-effect relationships between strategic constructs (also called strategic objectives [Kaplan and Norton 1996]). These linkages form "strategy maps" (Kaplan and Norton 2000), also called "value driver maps" (Ittner and Larcker 2003) or "causal chains of performance" (Tayler 2010). Downward links between *Conceptual Level* strategic constructs and *Operational Level* measures reflect the role of measures as imperfect representations of higher-level strategic constructs. Horizontal linkages at the *Operational Level* represent testable relationships between measures (based on the hypothesized relationships of the associated strategic constructs at the *Conceptual Level*). Figure 1 also captures the potential effect of exogenous factors, such as economic conditions, that influence the realization of performance measures.

Surrogation

Notwithstanding the many benefits of aligning a firm's strategic constructs with performance measures, this process can also lead managers to focus on performance measures to the point that they lose sight of the strategic constructs that the measures represent. Although intended as proxies for higher-level constructs, Ijiri (1967, 1975) identifies the potential for measures to replace the construct as the focus of interest. Ijiri (1967, 1975) provides an example of how investors use a firm's accounting measures to learn about the firm's economic viability (the construct of interest).[2] When strategic objectives are the constructs of interest, this phenomenon involves managers failing to fully appreciate the role of measures as mere representations of strategy, a phenomenon we label *surrogation*.

---

[2] A specific example of this phenomenon is seen in the relationship between accounting earnings and Hicksian income (Hicks 1939; Schipper and Vincent 2003). A firm's stakeholders rely on accounting earnings reported on the income statement to learn about the firm's Hicksian income. However, through repeated use of the earnings measure, investors may begin to act as though earnings, and not Hicksian income, is the construct of interest. Strong market responses to firms just missing earnings benchmarks (e.g., Burgstahler and Dichev 1997) is consistent with surrogation at the market level, and suggest that surrogation has non-trivial implications.

In some scenarios, surrogation is of little consequence. For example, if a construct is perfectly represented by a single measure or set of measures (Luft and Shields 2003; Farrell 2009), then the notion of surrogation is moot. However, because strategic constructs are typically ill-defined and complex, measures of constructs will be imperfect. That is, no single measure or set of measures perfectly captures the strategic construct in all scenarios to which the construct applies (Baker 1992, 2000; Bushman and Indjejikian 1993).

Surrogation may also be moot when complete contracts are in place. If a contract is designed such that a wealth-maximizing response yields optimal results in terms of the underlying constructs of interest, then employee beliefs about the true objective of the firm (maximize measure versus maximize construct) may be irrelevant. However, a growing body of work suggests that complete contracts are rarely seen in practice. Indeed, because of human limitations, firms must typically make trade-offs between contract completeness and contract complexity, such that the optimal contract is incomplete (Williamson 1985).

Notwithstanding these exceptions, surrogation is potentially detrimental in many scenarios, especially those in which the use of strategic performance measurement systems is most beneficial. For instance, suppose that a manager is charged with evaluating whether a customer-satisfaction focus increases financial performance. If the manager has used customer satisfaction survey scores as surrogates for customer satisfaction, and those scores suggest that satisfying customers does not improve financial results, then the manager may recommend moving away from a customer focus, rather than first evaluating the validity of the survey results. To the extent that the survey scores are an incomplete or imperfect proxy for the strategic construct of customer satisfaction, the decision to abandon the strategy could be suboptimal. Moreover, a manager who defines a strategic construct via an inherently imperfect measure may be less likely to recognize when the measure becomes obsolete, or may not perceive the benefits of a new measure that better captures the strategic construct in a changing business environment. Regardless of its "net" effect, the potential for the costs associated with surrogation to mitigate the effectiveness of the strategic performance measurement system highlights the need for a deeper understanding of the surrogation phenomenon.

Research in psychology provides a theoretical explanation for *why* managers use performance measures as surrogates for strategic constructs. In particular, Kahneman and Frederick (2002) discuss the notion of *attribute substitution*, which occurs when an individual has to make a judgment about a complex "target attribute," and instead relies on a more easily accessible "heuristic attribute" during the judgment process (see also Schkade and Kahneman 1998; Kahneman et al. 2006).[3]

Kahneman and Frederick (2002, 54) discuss three conditions necessary for attribute substitution to occur. First, the target attribute must be relatively inaccessible. Second, the heuristic attribute must be highly accessible. Third, the substitution of the target attribute with the heuristic attribute must not be consciously rejected. Strack et al.'s (1988) study highlights these three conditions. Strack et al. (1988) ask college students "How many dates did you have last month?" and "How happy are you with your life in general?" and manipulate the order of these questions between subjects. When students answered the happiness question first, the correlation between their answers to the two questions was negligible. However, when students answered the dating question first, the correlation jumped to 0.66. In this example, answering the happiness question first requires making a judgment about the relatively inaccessible attribute of overall happiness. When answering the happiness question second, students appeared to rely on the highly accessible and quantifiable number of dates they had last month to a greater extent than students answering the happiness question first. Though students may have been aware of their weighting of their dating success when assessing their overall happiness, their conscious processing did not reject this substitution.

---

[3] Kahneman and Frederick (2002) characterize attribute substitution as a general framework that includes multiple heuristics, including representativeness (Tversky and Kahneman 1974), availability (Tversky and Kahneman 1973), and recognition (Gigerenzer and Goldstein 1996). While surrogation fits within the same attribute substitution framework as the heuristics above, it is also distinct from these other phenomena. Although we rely on the attribute substitution framework to develop our theory, we retain the surrogation label to differentiate our phenomenon of interest from those noted above, and to more consistently reflect Ijiri's (1967, 1975) original discussion of how accounting measures originally developed to represent a construct to eventually replace the construct itself.

In the context of strategic performance measurement systems, the first of the three necessary conditions for attribute substitution is usually satisfied because strategic constructs are typically abstract, ill-defined, and complex. In this study, we consider how incentive compensation, a feature common to strategic performance measurement systems, influences the degree to which the *second* and *third* attribute-substitution conditions are met.[4]

Incentive Compensation

A large body of literature addressing the incentives-performance relationship suggests that a variety of mechanisms determine how incentives affect performance (Bonner and Sprinkle 2002). While no one theory provides a comprehensive explanation for how incentives ultimately influence performance, this research suggests that incentive compensation has attention-directing effects, which influence an individual's experience with performance measures (Atkinson et al. 1997; Lambert 2001). In this study, we investigate how linking managers' compensation to performance measures affects their tendency to use measures as surrogates for strategic constructs.

Incentive Compensation on a Single Performance Measure of a Strategic Construct

Prior research shows that firms often use multiple performance measures to represent a single strategic construct (Banker et al. 2000; Chen et al. 2010) and must decide on the number of strategically linked performance measures on which to provide financial incentives. This decision is non-trivial because firms must balance potentially conflicting factors such as contract completeness and contract complexity in their decisions (Ittner and Larcker 1998). As such, firms often choose to base incentives on only a subset of the available measures.

We first consider the basic context in which incentive compensation depends on a single measure of a strategic construct. Psychology literature demonstrates that individuals have limited attention, and that task structure can affect the attention given to features of the environment (James 1890; Shiffrin 1988). Consistent with this research, we posit that incentive compensation directs managers' limited attention toward the compensated measure as the means by which managers' actions affect their compensation, thereby influencing their strategy-implementation experience (Frederickson et al. 1999). These attention-directing effects of incentive compensation heighten the accessibility of the heuristic attribute, which is here the compensated measure, thereby increasing the likelihood of meeting the second necessary condition for attribute substitution. Further, although managers may recognize their use of a heuristic attribute in their assessment, we expect at least some of them not to reject this substitution. Thus, relative to a scenario in which measures are not used for compensation purposes, incentive compensation on a single measure of a strategic construct increases managers' propensity to exhibit surrogation. This leads to the following hypothesis:

---

[4] Kaplan and Norton (1996, 219) advocate tying employee compensation to strategic performance measurement systems, but caution that doing so can be problematic when measures "are not perfect surrogates for the strategic objectives."

> **H1:** Basing compensation on a single measure of a strategic construct leads managers to use the measure as a surrogate for the strategic construct more than they would under a fixed-wage-compensation scheme.

Incentive Compensation with Multiple Performance Measures of a Strategic Construct

Like compensation based on a single measure of a strategic construct, compensation based on multiple measures of a single strategic construct can also lead managers to view those measures as a means by which their actions determine their compensation. Thus, regardless of the number of compensated measures, a manager's attention is directed toward compensated measures, increasing the availability of these heuristic attributes. As with compensation based on a single measure, this heightened attention increases the likelihood of meeting the second necessary condition for attribute substitution. However, managers' attention toward, and experience with, multiple measures may be markedly different relative to when compensation is based on a single measure of a strategic construct. We focus on whether managers' experience with multiple measures will increase the likelihood that they will reject the substitution of the heuristic attribute for the target and, hence, fail to satisfy the third necessary condition for attribute substitution (Kahneman and Frederick 2002).

To the extent that multiple measures are relatively independent, managers compensated on multiple measures confront a greater number of action trade-offs that influence their compensation than managers compensated on a single measure (Wood 1986; Campbell 1988; Bonner 1994). To simplify the action-choice task (Payne et al. 1993) managers likely use similarity assessments, which facilitate object classification, concept formation, and related judgments and decisions (Tversky 1977; Fiske and Taylor 1991). Consistent with this theory, we posit that managers compensated on multiple measures of a single strategic construct will consider the similarities of these measures. In doing so, managers are likely to obtain greater awareness of the overall strategic construct and the extent to which the measures represent the strategic construct. This mechanism occurs in two ways. First, comparing the compensated measures increases the likelihood that managers will realize that all of the compensated measures represent the same strategic construct (Johnson 1988; Markman and Medin 1995; Shah and Oppenheimer 2011). Second, comparing the compensated measures highlights the limited ability of any one measure to completely represent the corresponding strategic construct (Zhang and Markman 2001). Thus, by performing these similarity assessments, managers will attend more to the representational role of the measures as proxies for a related strategic construct relative to a setting with a single compensated measure. This increases the likelihood that managers will reject the tendency to replace the strategic construct with performance measures.

Compensation on multiple measures could increase the tendency to use simplifying heuristics and thus increase the accessibility of heuristic attributes, which affects the second necessary condition for attribute substitution. However, such compensation also brings conscious operations into play that increase the likelihood that the substitution of the target attribute with the heuristic attribute will be rejected, reducing the likelihood that the third necessary condition for attribute substitution will be satisfied (Chaiken 1980; Schwarz 2004; Alter et al. 2007). Therefore, we hypothesize that managers compensated on multiple measures of a strategic construct are less likely to exhibit surrogation than those compensated on a single measure of a strategic construct.

> **H2:** Basing compensation on multiple performance measures of a single strategic construct leads managers to use compensated measures as surrogates for the strategic construct less than they would under a single-measure compensation scheme.

III. METHOD

We tested our hypotheses in a laboratory experiment in which participants used computers to work through self-guided instructions and perform various tasks. Participants in our main experiment were 79 students recruited from graduate business courses at a highly ranked business school in the United States. On average, participants were 29 years old, and 61 percent were male.

Experimental Task

After an introduction to the study, participants designed a virtual creature using the *Creature Creator* module of the computer game *Spore* (Electronic Arts 2008; Lawton 2008). Instructions indicated that participants should use the following strategy for designing their creature:

> Design a creature that can socialize with other life forms such that it will become the dominant species on the planet.[5]

Figure 2 provides a sample screen similar to what participants viewed. At the outset of this first task in the experiment, participants received an endowment of 500 "DNA points," with which to purchase various body parts for their creature.[6] Each part added one or more abilities to the creature. Participants could see what abilities each part added before purchase, as well as measures of each ability in real-time as they added each part. When a part was added to the creature, the cost of the part was automatically deducted from the participant's DNA point endowment. If a participant removed a part from the creature, then the program immediately adjusted the creature's ability measures and refunded the participant's DNA points.

While designing their creature, participants saw numerous measures of their creature's abilities, including four measures tied to their creature's ability to "socialize," the strategic construct of interest.[7] These quantitative measures reflected the creature's ability to *sing*, *dance*, *charm*, and *pose* (each on a scale of 0 to 5). Instructions indicated that each of these abilities was equally important to their creature's ability to socialize.

All participants received compensation based on a post-experimental assessment of their creature's ability to achieve global domination via socialization. This compensation allowed us to hold constant, across all conditions, the incentive to design a creature in line with the provided strategy. We calculated participant compensation after the completion of the experimental session. A research assistant placed each participant's creature individually in a *Spore* environment, gave simple commands to the creature to befriend neighboring creatures, and recorded the time needed to befriend two creatures.[8] Within each experimental condition, we compared the performance of each

---

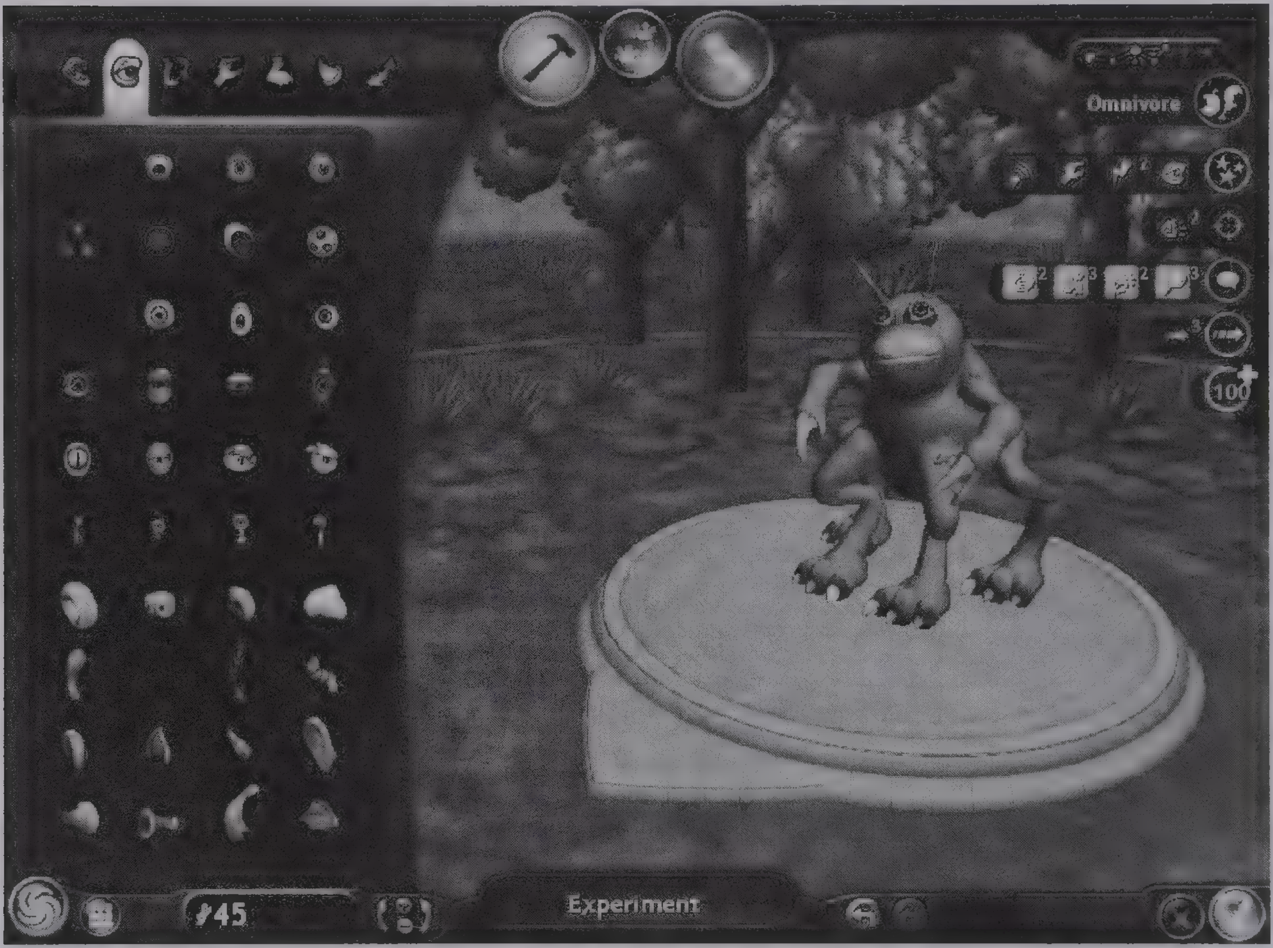
[5] The concepts of "socializing" and becoming "dominant" in this strategy statement may seem at odds with each other. To clarify, we provided participants with a general introduction to the game of *Spore*, which highlighted two strategies for becoming the dominant species: "You can become the dominant species by making friends with other species, or by overpowering them." We provided this information to participants to mitigate any confusion over features of the *Spore* software unrelated to the experimental task. To further ensure that participants understood the general *Spore* introduction and the specific instructions for the experimental task, we required all participants to correctly answer a question indicating that social abilities were most important to their creature's ability to achieve global domination in the task. Any confusion that may have persisted should work against our finding support for our directional predictions.

[6] This budget limit (500 DNA points) served to ensure that participants had enough resources to design a creature in line with the provided strategy, but not without making trade-offs. That is, given this resource constraint, participants had to choose among multiple ways of implementing the stated strategy.

[7] Measures of other abilities inherent to the *Spore* software, but unrelated to our experimental task, were also visible to participants. To avoid confusion, all available measures were described in the instructions. Availability of all measures was held constant across all experimental conditions.

[8] A creature's total social-ability level (i.e., the sum of a creature's *sing*, *dance*, *charm* and *pose* levels) is a key determinant of its time to befriend, as creatures with lower measure levels take longer to befriend other creatures.

FIGURE 2
Screenshot of Initial Creature Design



Above is a sample screenshot of the *Creature Creator* module of the computer game *Spore*. The left side of the screen displays various body parts that can be added to the creature. The upper-right corner of the screen displays various measures of the creature's abilities. The third row of boxes on the upper right displays the four social-ability measures: *sing* (level = 2), *dance* (level = 3), *charm* (level = 2), and *pose* (level = 3). During the experiment, these measures were constantly available and were adjusted real-time as participants added and removed parts from their creatures. "DNA points," used as currency to purchase parts, are displayed in the bottom-left corner of the screen (currently DNA = 45). Buttons at the top center of the screen allow participants to paint their creature and to see their creature move in a simple environment.

participant's creature to that of nine other randomly selected participants' creatures, and this relative performance ranking determined one portion of their compensation. The top performer in each group earned \$20, the second best performer received \$18, etc. Providing compensation tied directly to successful implementation of the strategy helped reinforce the equal importance of all four measures in minimizing the time to befriend two creatures. By heightening participants' awareness of all four social-ability measures, including this compensation works against finding evidence of surrogation in our experiment.

Note that neither "time to befriend" nor the related tournament-based compensation serve as our dependent variable. Although these variables may indirectly capture the extent to which participants use measures as surrogates for the strategy, they also reflect participants' desire to maximize wealth. Consequently, using these variables introduces a wealth-maximization confound that would limit our ability to test the effect of incentives on surrogation. For this reason, we constructed an alternative dependent variable that does not suffer from this confound, which we describe following the discussion of our independent variable.

Independent Variable

In addition to the compensation tied to the participant's success at strategy implementation, some participants received incentive compensation tied directly to measures of their creature's social-ability. This compensation is our independent variable, which we manipulate at three levels: no social-ability compensation (*fixed-wage-compensation*), compensation tied to a single measure of the creature's social-ability (*single-measure-compensation*), and compensation tied to three of the four social-ability measures (*multiple-measure-compensation*). In the fixed-wage-compensation condition, participants received \$10 regardless of their creature's social-ability measures. In the single-measure-compensation condition, participants received \$2 per level of their creature's *sing* measure. For example, a participant who designed a creature with *sing* level 4 would receive 4 × \$2 = \$8. In the multiple-measure-compensation condition, participants received \$1 per level of their creature's *sing*, *dance*, and *charm* measures. For example, a participant who designed a creature with *sing* level 3, *dance* level 2, and *charm* level 4, would receive (3 × \$1) + (2 × \$1) + (4 × \$1) = \$9.

Dependent Variables

We elicited our primary dependent measure using a second task after participants finished designing their virtual creature. To elicit this dependent measure, participants viewed 18 successive pictures of other virtual creatures. With each of these creatures, participants saw two potential combinations of the four social-ability measures (*sing*, *dance*, *charm*, and *pose*). We labeled these combinations as "modification packages." As they viewed each creature, participants selected the modification package that they believed would best implement the stated strategy from the initial creature design task of the experiment. In addition, the instructions indicated that participants should assume that the DNA cost was equal across each pair of modification packages. Participants viewed each of the 18 creatures one at a time, and made their modification-package selections as they viewed each creature. Once participants selected a modification package and moved on to the next creature, they could not go back and change earlier modification-package selections. Figure 3 depicts an example of what participants saw as they made these selections.[9]

We designed modification-package pairings *ex ante* to allow us to use participants' selections to evaluate the extent to which our compensation manipulation influenced participants' tendency to use compensated measures as surrogates for strategy. To illustrate, consider the sample pairing presented in Figure 3, which includes the following two modification-package options:

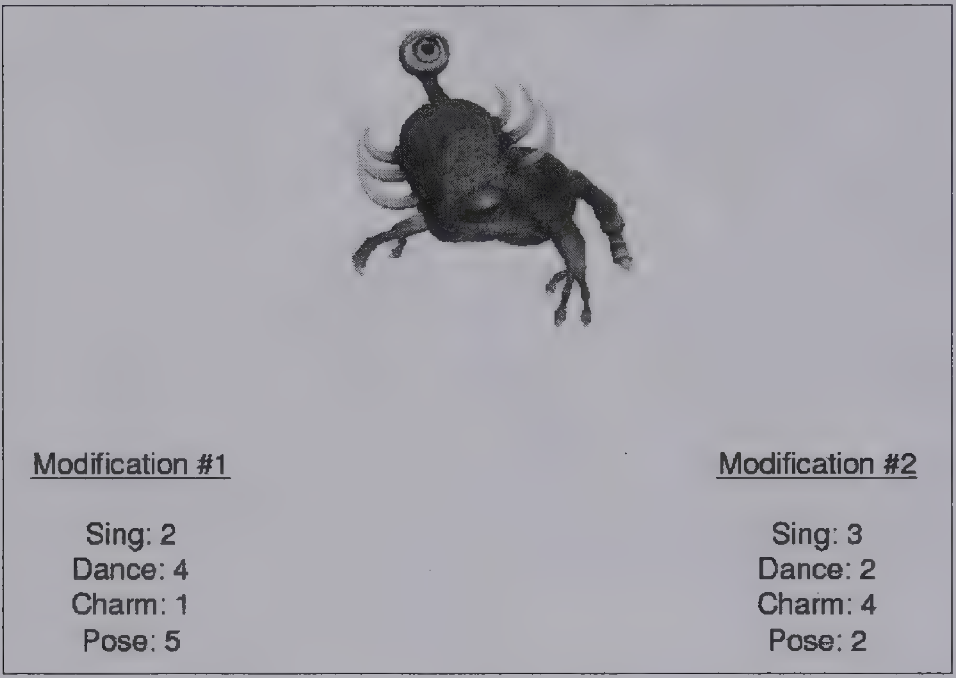
Modification package #1: *sing* = 2, *dance* = 4, *charm* = 1, and *pose* = 5.
Modification package #2: *sing* = 3, *dance* = 2, *charm* = 4, and *pose* = 2.

Given this pairing, if a participant selects modification package #2, then this selection is consistent with the goal of maximizing *sing*, because *sing* is 2 in modification package #1 and is 3 in modification package #2. Thus, selecting modification package #2 is consistent with surrogation with *sing*. Selecting modification package #2 is also consistent with the goal of maximizing *sing*, *dance*, and *charm*, because the sum of those three abilities is 7 in modification package #1 and is 9

---

[9] To control for an order effect, we created four randomly determined orders for the 18 choices, and fully crossed these four order conditions with our three compensation conditions. The order in which choices are made does not alter our results. Thus, we ignore this variable in subsequent analyses and discussion.

FIGURE 3
Sample Modification-Package Choice



Modification #1

Sing: 2
Dance: 4
Charm: 1
Pose: 5

Modification #2

Sing: 3
Dance: 2
Charm: 4
Pose: 2

Above is a sample of one of the 18 modification-package pairings used to generate the primary dependent variable for the study. For each pairing, participants were shown a picture of a creature along with the two modification packages. Participants were asked to select the modification package that they believed, if added to the creature, would best enable them to implement the provided strategy. After making their selection, participants clicked "Next" to move on to the next creature and modification-package pairing.

in modification package #2. Thus, selecting modification package #2 is also consistent with surrogation with *sing*, *dance*, and *charm*.

To construct our primary dependent variable, we sum the number of selections a participant makes that are consistent with surrogation. In determining whether a selection is consistent with surrogation, we focus on behavior as it pertains to the social-ability measure(s) for which participants had previously earned compensation during the creature-design task of the experiment. Thus, for single-measure-compensation participants, we focus on their behavior as it pertains to the *sing* measure, and investigate whether participants' selections maximize *sing*. For multiple-measure-compensation participants, we focus on their behavior as it pertains to the *sing*, *dance*, and *charm* measures, and investigate whether participants' selections maximize the sum of *sing*, *dance*, and *charm*.

Although all participants saw the same 18 creatures and associated modification-package pairings, not all 18 pairings can be used to measure behavior consistent with surrogation. For example, a pairing in which *sing* is the same in both modification packages cannot be used to measure surrogation with *sing*. Similarly, a pairing in which the sum of *sing*, *dance*, and *charm* is the same in both modification packages cannot be used to measure surrogation with *sing*, *dance*, and *charm*. Thus, we divide the number of selections a participant makes that are consistent with surrogation in their experimental condition by the number of pairings that can be used to evaluate surrogation in that condition to come up with a participant's "comprehensive surrogation score."

TABLE 1
Modification-Package Pairings

12	5	2	1	3	8	11	2	4	2	5	8	13	Yes	No	Yes
13	2	4	3	2	9	11	2	5	1	3	8	11	No	Yes	No
14	3	5	4	2	12	14	3	1	5	5	9	14	No	Yes	No
15	4	3	4	1	11	12	4	1	3	5	8	13	No	Yes	Yes
16	2	4	3	1	9	10	2	1	5	5	8	13	No	Yes	Yes
17[d]	5	1	4	1	10	11	4	3	2	1	9	10	No	No	NA
18[d]	3	3	2	2	8	10	3	4	1	3	8	11	No	No	NA

This table lists the 18 modification-package pairings provided to participants. Although pairings are numbered in the table, they were not numbered in the study, and were presented in four, predetermined, random orders (order is fully crossed with the compensation manipulation).

[a] The column labeled "Surrogation-Consistent Modification Package" gives the levels of *sing* (S), *dance* (D), *charm* (C), and *pose* (P) of the modification package within each pairing that represents an option consistent with surrogation with *sing*, surrogation with *sing*, *dance*, and *charm*, or both. The column labeled "Alternative Modification Package" gives the alternative to the surrogation-consistent option. Although not shown in the table, modification packages are labeled for each pairing as "Modification #1" or "Modification #2" (see Figure 3). In addition, the label on the surrogation-consistent modification package is randomly determined, and is held constant for all participants.

(continued on next page)

TABLE 1 (continued)

[b] The table also shows whether the pairing is used to evaluate surrogation with *sing* or surrogation with *sing*, *dance*, and *charm*. For example, in Pairing #9, a choice of the modification package listed in the "Surrogation-Consistent Modification Package" column is consistent with surrogation with *sing*, because it has a higher *sing* level than the alternative. However, this pairing is not used to evaluate surrogation with *sing*, *dance*, and *charm*, as the total of these three measures is equal across modification packages in this pairing. However, Pairing #5 can be used to evaluate both surrogation with *sing*, and with *sing*, *dance,* and *charm*, because one package is dominant on both *sing* and on the total of the *sing*, *dance,* and *charm* measures.

[c] The last column indicates whether there is an opportunity cost to selecting the surrogation-consistent Modification Package. *No opportunity cost* pairings are comprised of modification packages in which the total level of the four social-ability measures are equal between the two modification packages. Thus, a participant who chooses the modification package consistent with surrogation incurs no cost to do so. In contrast, *opportunity cost* pairings are comprised of modification packages in which the total level of the four social-ability measures are lower for the surrogation-consistent option than for the alternative.

[d] Pairings #17 and #18 are not used in any test of surrogation. These pairings are included in the experiment as distracters. For Pairing #17, the modification package with higher *sing*, and *sing*, *dance*, and *charm* levels also has a higher total across all four social-ability measures, confounding surrogation and optimal-card selection. For Pairing #18, both *sing* and the total of *sing*, *dance*, and *charm* are equal across packages, so there is no surrogation-consistent modification package for this pairing.

Twelve of the 18 pairings are relevant for evaluating participants' tendency to use *sing* as a surrogate for social-ability, the strategic construct. A different set of 12 pairings are relevant for evaluating participants' tendency to use *sing*, *dance*, and *charm* as surrogates for social-ability. Table 1 presents the 18 modification-package pairings, along with a breakdown of the relevant pairings for measuring behavior consistent with surrogation in each experimental condition.

Modification-package pairings differed according to the extent to which participants had to incur an opportunity cost to make a selection consistent with surrogation. We label pairings in which the total level of the four social-ability measures (*sing*, *dance*, *charm*, and *pose*) is equal between the two modification packages as *no opportunity cost* pairings. With these pairings, a participant selecting the modification package consistent with surrogation does not forgo a higher total social-ability (i.e., incurs no opportunity cost) to do so. In contrast, we label pairings in which the surrogation-consistent modification package has a lower total social-ability level as *opportunity cost* pairings. With these pairings, a participant selecting the surrogation-consistent modification package incurs an opportunity cost because a creature's total social-ability level is a key determinant of its ability to achieve the strategic objective of socializing with other creatures.[10] To illustrate, consider again the pairing shown in Figure 3. While modification package #2 maximizes the *sing* level because *sing* is 2 in modification package #1 and is 3 in modification package #2, modification package #1 has a higher total social-ability level because *sing*, *dance*, *charm*, and *pose* levels sum to 12 for modification package #1 and sum to 11 for modification package #2. Therefore, selecting the surrogation-consistent modification package in this example entails forgoing higher total social-ability, and is thus categorized as an opportunity cost pairing. The last column in Table 1 indicates the opportunity cost status of each of the surrogation-consistent modification package pairings.

In summary, we compute three measures of surrogation: *comprehensive*, *no opportunity cost*, and *opportunity cost*. As described above, we compute these three measures differently depending on how participants were compensated in the creature-design task. Specifically, we measure single-measure-compensation (multiple-measure-compensation) participants' propensity to use *sing* (*sing*, *dance*, and *charm*) as a surrogate for social-ability. We compute both versions of these measures for the fixed-wage-compensation participants to allow for baseline measures of surrogation against which the other conditions can be compared.

Session Timeline

As participants arrived at a session, we randomly assigned them to one of the three compensation conditions. Participants read computer-based instructions and watched a video tutorial on using the *Creature Creator* module of *Spore*. Participants then practiced building a virtual creature for 12 minutes. After practicing, participants read additional instructions that included information about participants' compensation and the strategy to be implemented, took a short quiz to ensure their understanding of the instructions, and then proceeded to design their virtual creatures. Next, participants viewed the 18 modification-package pairings, and made their selections for each pairing. Finally, participants completed a questionnaire to elicit demographic and process-related information. We debriefed and compensated participants after all sessions were completed.

---

[10] Our use of the label "opportunity cost" is not intended to convey that participants incurred a direct financial cost in choosing one of the modification packages. Rather, our intention in our main experiment is to differentiate pairings in which a surrogation-consistent selection forgoes something of value in executing the strategy (i.e., a creature with a higher total social-ability level).

Additional Discussion of the Experimental Design

A number of issues relating to our experimental design warrant further discussion. First, each of the four social-ability measures completely captures non-overlapping dimensions of the social-ability construct. While at odds with our contention that no single measure or set of measures perfectly captures the strategic construct across all real-world settings in which the construct applies, this design feature allows for a clean test of our hypotheses. Importantly, this design choice highlights the incomplete nature of the compensation contract in all three experimental conditions. A complete contract in our setting would place positive and equal incentive weights on all four social-ability measures. However, as discussed earlier, our compensation schemes are meant to reflect real-world settings in which incomplete contracts are common (Williamson 1985).

Second, we provide no compensation for participants' modification-package selections. Single- or multiple-measure-based compensation similar to that provided to participants during the creature-design task of the experiment would introduce a "wealth maximization" confound, precluding us from observing the phenomenon of interest. Thus, we use an experimental setting that is admittedly different from many real-world settings involving incentives. Indeed, although real-world settings that parallel our experimental setting likely exist (e.g., see Malina and Selto 2004), our experimental setting is not meant to map into any specific real-world setting. Rather, our intent is to create a setting that yields a valid measure of surrogation and a clean test of our hypotheses. However, the results of our main study speak directly to settings where managers must make strategic decisions without having compensation tied directly to every aspect of decision-making.[11,12] Further, to address alternative explanations for our results, we conduct an additional experiment in which we compensate participants for strategically aligned modification-package selections. We discuss this follow-up experiment and associated results in Section IV.

Third, the single-measure-compensation scheme and the multiple-measure-compensation scheme differ not only in terms of the number of compensated measures (our manipulation of interest), but also in terms of the representativeness of the compensated measures. In general, the better the set of measures used for decision making represents strategy, the better the strategic decisions will be. However, our theory focuses on the effect of the number of compensated measures on *surrogation*, and not on the increase in the optimality of strategy-related decisions induced by greater representativeness. Thus, if we chose to measure surrogation behavior indirectly

---

[11] One potential concern is that, absent incentives, participants in all conditions may exert minimal effort when making their modification-package selections. Notably, low effort works against finding support for our directional predictions, as low effort increases noise in our dependent measures across all conditions. Additionally, if participants exerted minimal effort and selected modification packages randomly, then they would select the surrogation-consistent option about half the time. In contrast, high effort implies a lower likelihood that participants select the surrogation-consistent option. In all three conditions, participants selected the surrogation-consistent option significantly *less* than half the time ($p < 0.01$ in all cases). Furthermore, within each condition, participants chose the surrogation-consistent option significantly more often for *no opportunity cost* pairings than for *opportunity cost* pairings ($p < 0.01$ in all cases), providing additional evidence of an effortful evaluation in this task.

[12] Relatedly, Holmstrom and Milgrom (1991) analyze a model wherein an employee is charged with performing multiple tasks. They show that compensating on only a subset of tasks induces the employee to allocate attention to the compensated tasks at the expense of those tasks that are not compensated, resulting in unbalanced task performance. Our analysis differs from Holmstrom and Milgrom (1991) in that compensation in our study is also expected to lead to an unbalanced interpretation of the strategic construct with the number of compensated measures moderating this effect. Further, our primary dependent variable goes beyond wealth-maximizing behavior to capture surrogation-related behavior induced by the attention-directing effects of incentive compensation. Thus, our study complements Holmstrom and Milgrom (1991) by suggesting additional, but separate, effects of tying compensation to a subset of available measures.

via a measure of decision optimality, then disentangling the effects of multiple-measure-compensation and the representativeness of compensated measures would not be possible (because both are expected to influence decision optimality). However, our dependent variable captures surrogation independent of decision optimality by measuring the tendency to ignore non-compensated measure(s). By constructing our dependent variable in this way, the greater degree of representativeness of the compensated measures in the multiple-measure-compensation condition works against finding support for our hypotheses. Specifically, surrogation in the single-measure-compensation condition involves attending to a smaller proportion of social-ability than surrogation in the multiple-measure-compensation condition. Consequently, to the extent that representativeness of the compensated measures influences participants' judgments and decisions, participants in the single-measure-compensation condition are more likely to recognize that the compensated measure is insufficient in terms of its representativeness, decreasing participants' propensity to use the compensated measures as surrogates for social-ability.

Fourth, our use of the computer game *Spore* for our experimental instrument helps protect against the possibility that participants' priors regarding appropriate surrogates for strategic constructs affected their judgments and decisions, because the setting is far removed from most participants' practical and educational experiences. Importantly, however, the setting still allows participants to "get their hands dirty" implementing the provided strategy and to deal with various associated measures.[13]

Finally, we took several steps to maximize the internal validity of our study. To ensure that the strategy statement was salient, we explicitly stated the strategy on two occasions, the latter of which occurred immediately before participants designed their creature. We also included in the task instructions an explicit statement that all four measures of social-ability are equally important in implementing the strategy and achieving global domination. Further, participants had to demonstrate thorough understanding of the various aspects of our research design via a quiz.[14]

IV. RESULTS

We begin with an analysis related to the effectiveness of our incentive compensation manipulation. To assess whether participants performed the initial creature design task consistently with the provided incentives, we asked each participant to "indicate how much attention you gave to the [*sing*, *dance*, *charm*, and *pose*] abilities, by allocating 100 points among the four abilities. Allocate more points to abilities to which you gave more attention." We compared the mean number of points allocated either to *sing*, or to *sing*, *dance*, and *charm* across conditions (reported in Table 2). Not surprisingly, single-measure-compensation participants allocated more points (i.e., paid more attention) to the *sing* measure ($n = 26$, mean $= 35.1$ percent) than fixed-wage-compensation participants ($n = 27$, mean $= 22.4$ percent) ($t = 3.44$, $p < 0.01$).[15] Likewise, multiple-measure-compensation participants allocated more points to the *sing*, *dance*, and *charm* measures ($n = 26$, mean = 86.2 percent) than fixed-wage-compensation participants (mean 81.1 percent) ($t = 1.98$, $p = 0.03$).[16,17] Collectively, these results suggest that our compensation manipulation was successful.[18] We now turn to our hypothesis tests and related supplemental analyses.

---

[13] None of the participants reported any prior *Spore* experience. Further, experience playing video games is not a significant predictor of any of the results in our paper.

[14] Two quiz questions addressed the strategy statement and the equal importance of each ability measure. One multiple-choice question read, "Which of the following will help your creature achieve global domination most rapidly?" Options were "The ability to fly," "Social abilities," "Attack abilities," and "The ability to jump." Participants could not proceed until they gave the correct response ("Social abilities"). The other question read, "In *Spore*, which of the following is most important in determining your creature's ability to make friends with other creatures?" Options were *sing*, *dance*, *charm*, *pose*, and "All socializing abilities are equally important in determining a creature's ability to make friends." Again, participants could not continue until they gave the correct responses ("All socializing abilities are equally important in determining a creature's ability to make friends.").

[15] We report one-sided p-values for tests of directional predictions. Otherwise, we report two-sided p-values.

Primary Tests of Hypothesis 1

H1 predicts that compensation on a single measure of a strategic construct increases managers' propensity to use a measure as a surrogate for the strategic construct relative to a fixed-wage-compensation scheme. To test this hypothesis, we examine fixed-wage-compensation and single-measure-compensation participants' surrogation scores. H1 predicts that, relative to fixed-wage-compensation participants, single-measure-compensation participants are more likely to choose modification packages with higher levels of the *sing* measure, at the expense of other, equally important, social-ability measures. Such behavior would be consistent with surrogation.

To test H1, we first calculate participants' *comprehensive* surrogation scores—the percentage of each participant's modification-package choices that are consistent with surrogation with *sing* as described in Section III. Next, we compare the mean *comprehensive* surrogation score between fixed-wage-compensation and single-measure-compensation conditions. At the operational level, H1 is supported if single-measure-compensation participants' surrogation scores are higher than fixed-wage-compensation participants' surrogation scores. Participants' mean *comprehensive* surrogation score is 0.59 in the single-measure-compensation condition, but is only 0.39 in the fixed-wage-compensation condition (see Table 3, Panel A). As we report in Table 3, Panel B, the difference of 0.20 in *comprehensive* surrogation scores across these two conditions is statistically significant ($t = 4.56$, $p < 0.01$).

These results are robust to distinguishing surrogation scores in terms of whether there is an opportunity cost associated with selecting a surrogation-consistent modification package. Panel A of Table 3 presents participants' *opportunity cost* and *no opportunity cost* surrogation scores. As reported in Panel B of Table 3, mean *opportunity cost* and *no opportunity cost* surrogation scores

---

[16] Participants in the single-measure-compensation condition designed creatures with a higher level of *sing* (mean = 3.81) than participants in the fixed-wage-compensation condition (mean = 2.96) ($t = 2.98$, $p < 0.01$). However, participants in the multiple-measure-compensation condition (mean = 8.88) did not design creatures with higher combined levels of *sing*, *dance*, and *charm* than participants in the fixed-wage-compensation condition (mean = 8.41) ($t = 0.80$, ns), though the means are directionally consistent with the expected influence of incentives. This latter result likely stems from parameters inherent to the *Spore* software that lead to a small difference between the sum of the *sing*, *dance*, and *charm* levels for a participant maximizing on those measures and a participant maximizing on all four social-ability measures. This constraint is one reason why we elicited participants' self-reported point (i.e., attention) allocations.

[17] Although our hope in using an abstract environment was to limit preconceived notions about appropriate surrogates for strategy, participants nonetheless judged *charm* to be especially important for their creatures' social-ability. On average, participants allocated more points to *charm* than any other social-ability. This works against our finding results, as it adds noise to every condition. It specifically works against our finding support for H2, as an emphasis on *charm* would increase, not decrease, the tendency to use measures as surrogates for the strategic construct in our multiple-measure-compensation condition.

[18] Participants' total compensation did not differ across conditions ($F = 0.97$, ns). We designed our experiment to maximize the likelihood that, on average, creature design compensation and the additional compensation were approximately equal. The proportion of total compensation stemming from the creature design compensation for the fixed-wage-compensation, single-measure-compensation, and multiple-measure-compensation conditions were 50.5 percent, 43 percent, and 48 percent, respectively. The lower proportion in the single-measure-compensation condition stems from the fact that the mean creature-design compensation was higher in both the multiple-measure-compensation (mean = \$8.88) and the fixed-wage-compensation (mean = \$10.00) conditions than in the single-measure-compensation condition (mean = \$7.62).

TABLE 2

Responsiveness to Incentive Compensation Manipulation

Panel A: Mean Creature Design Point Allocations[a] (Standard Deviation)

	Compensation Condition[b]		
Social-Ability Measures	**Fixed-Wage Compensation (n = 27)**	**Single-Measure Compensation (n = 26)**	**Multiple-Measure Compensation (n = 26)**
Sing	22.4 (7.6)	35.1 (17.6)	26.7 (7.3)
Dance	23.8 (8.6)	17.9 (7.0)	26.5 (9.6)
Charm	34.9 (16.9)	34.5 (19.1)	33.0 (14.5)
Pose	19.2 (8.9)	12.5 (7.5)	13.9 (9.5)

Panel B: Statistical Tests

	Estimate	**t**	**p-value[c]**
Points Allocated to *sing*: Fixed-Wage versus Single-Measure Compensation	12.7	3.44	< 0.01
Points Allocated to *sing*, *dance*, and *charm*: Fixed-Wage versus Multiple-Measure Compensation	5.1	1.98	0.03

[a] *Creature Design Point Allocations* represent participants' allocations of exactly 100 points across the four social-ability measures—*sing*, *dance*, *charm*, and *pose*—when asked to "indicate how much attention you gave to the [*sing*, *dance*, *charm*, and *pose*] abilities, by allocating 100 points among the four abilities. Allocate more points to abilities to which you gave more attention."

[b] This represents compensation tied directly to social-ability measures of the creatures initially designed by participants. We manipulated this source of compensation at three levels: no social-ability compensation (*fixed-wage-compensation*), performance-based compensation based on a single measure of the creature's social abilities (*single-measure-compensation*), and performance-based compensation based on three of the four measures of the creature's social abilities (*multiple-measure-compensation*). In the fixed-wage-compensation condition, participants received \$10 regardless of the state of their creature's social-ability measures. In the single-measure-compensation condition, participants received \$2 per level of their creature's *sing* measure (e.g., a level 4 *sing* measure resulted in compensation of \$8). In the multiple-measure-compensation condition, participants received \$1 per level of their creature's *sing*, *dance*, and *charm* measures (e.g., a creature with *sing* level 3, *dance* level 2, and *charm* level 5 resulted in compensation of \$10).

[c] All p-values are presented on a one-tailed basis, given the expected influence of incentive compensation.

are higher in the single-measure-compensation condition than in the fixed-wage-compensation condition (*opportunity cost*: $t = 2.49$, $p = 0.01$; *no opportunity cost*: $t = 4.15$, $p < 0.01$).[19]

Collectively, these results support our hypothesis that compensation on a single measure of a strategic construct increases managers' propensity to use the compensated performance measures as

---

[19] As discussed earlier, our *opportunity cost* surrogation scores measure participants' tendency to sacrifice a high overall social-ability for higher levels of the compensated measures. However, participants could also have viewed low variance among social abilities as desirable. As such, opportunity cost surrogation may reflect sacrificing low social-ability variance to maximize the compensated measures. For both hypotheses, untabulated results investigating this possibility are inferentially identical to those of our main analyses.

TABLE 3

Tests of Hypotheses

Panel A: Mean Surrogation Scores (Standard Deviation)

	Compensation Condition[a]		
Surrogation Scores	**Fixed-Wage Compensation (n = 27)**	**Single-Measure Compensation (n = 26)**	**Multiple-Measure Compensation (n = 26)**
Surrogation Score: Comprehensive[b]	0.39[e] (0.12)	0.59 (0.19)	0.46 (0.25)
Surrogation Score: No Opportunity Cost[c]	0.62[e] (0.20)	0.84 (0.18)	0.63 (0.26)
Surrogation Score: Opportunity Cost[d]	0.15[e] (0.23)	0.34 (0.32)	0.29 (0.31)

Panel B: Hypothesis Tests

	Estimate	**t**	**p-value[f]**
H1: Fixed Wage versus Single-Measure			
Comprehensive	0.20	4.56	< 0.01
No Opportunity Cost	0.22	4.15	< 0.01
Opportunity Cost	0.19	2.49	0.01
H2: Single-Measure versus Multiple-Measure			
Comprehensive	−0.13	2.15	0.02
No Opportunity Cost	−0.21	3.38	< 0.01
Opportunity Cost	−0.05	0.58	ns

---

[a] Compensation condition represents compensation tied directly to social-ability measures of the creatures initially designed by participants. We manipulated this source of compensation at three levels: no social-ability compensation (*fixed-wage-compensation*), performance-based compensation based on a single measure of the creature's social abilities (*single-measure-compensation*), and performance-based compensation based on three of the four measures of the creature's social abilities (*multiple-measure-compensation*). In the fixed-wage-compensation condition, participants received $10 regardless of the state of their creature's social-ability measures. In the single-measure-compensation condition, participants received $2 per level of their creature's *sing* measure (e.g., a level 4 *sing* measure resulted in compensation of $8). In the multiple-measure-compensation condition, participants received $1 per level of their creature's *sing*, *dance*, and *charm* measures (e.g., a creature with *sing* level 3, *dance* level 2, and *charm* level 5 resulted in compensation of $10).

[b] *Comprehensive* surrogation scores are the percentage of participants' modification-package choices that are consistent with surrogation with *sing* or with *sing*, *dance*, and *charm*, depending on the compensation condition.

[c] *No Opportunity Cost* surrogation scores are the percentage of participants' modification-package choices that are consistent with surrogation with *sing* or with *sing*, *dance*, and *charm*, depending on the compensation condition, when the total of all four social-ability measure levels does not differ between modification packages.

[d] *Opportunity Cost* surrogation scores are the percentage of participants' modification-package choices consistent with surrogation with *sing* or with *sing*, *dance*, and *charm*, depending on the compensation condition, given that such a choice means forgoing a higher total level of the four social-ability measures.

[e] Because H1 requires a comparison of surrogation with *sing* between the fixed-wage-compensation and single-measure-compensation conditions, the surrogation scores for the fixed-wage-compensation condition for this table are based on surrogation with the *sing* measure.

[f] All p-values are presented on a one-tailed basis, given the directional predictions of H1 and H2.

a surrogate for the strategic construct. Especially interesting is the robustness of these results when considering choices where surrogating with *sing* entails incurring an opportunity cost. Further, these results cannot be explained by a simple propensity toward wealth-maximization, because participants were not paid to maximize a subset of the available measures during this task of the experiment (see Section III).

Primary Tests of Hypothesis 2

H2 predicts that compensation on multiple measures of a strategic construct leads managers to use the compensated measures as surrogates for the strategic construct less than if they are compensated on a single measure. Operationally, this suggests that participants in the multiple-measure-compensation condition will exhibit lower surrogation scores than participants in the single-measure-compensation condition.

In calculating surrogation scores, we focus on the social-ability measures for which participants received compensation while designing their initial virtual creature. Thus, for single-measure-compensation participants, we use the same surrogation scores used to test H1, which are computed based on their surrogation with *sing*. For multiple-measure-compensation participants, we compute surrogation scores based on choices related to the sum of the *sing*, *dance*, and *charm* measure levels. Participants' mean *comprehensive* surrogation score is 0.59 in the single-measure-compensation condition, but is only 0.46 in the multiple-measure-compensation condition (see Table 3, Panel A). As we report in Table 3, Panel B, the difference of 0.13 is significant ($t = 2.15$, $p = 0.02$). These results are robust when considering the *no opportunity cost* surrogation score ($\text{mean}_{\text{single}} = 0.84$; $\text{mean}_{\text{multiple}} = 0.63$; $t = 3.38$, $p < 0.01$). With respect to the *opportunity cost* surrogation score, however, the results are not statistically significant ($\text{mean}_{\text{single}} = 0.34$; $\text{mean}_{\text{multiple}} = 0.29$; $t = 0.58$, ns). Importantly, the comparison of *no opportunity cost* surrogation scores provides the most conservative test of H2. That is, choices consistent with surrogation are *most* likely to be made when surrogation is *not* costly. Thus, our results suggest that multiple-measure-compensation participants are less likely than single-measure-compensation participants to make such choices, but only in the absence of opportunity costs. These results thereby provide some evidence consistent with H2.

A concern regarding our tests of H2 is that these tests entail using a different subset of modification-package pairings across compensation conditions. That is, the *comprehensive*, *no opportunity cost*, and *opportunity cost* surrogation scores are computed using different subsets of modification-package pairings across the single-measure- and multiple-measure-compensation conditions. To control for this inherent lack of consistency, we also test H2 using pairings that are used to compute surrogation scores for both of these compensation conditions (Pairings #1–8 in Table 1). Based on these alternative measures, untabulated results for the *comprehensive* and *no opportunity cost* surrogation scores are inferentially identical to those initially reported. For the alternative *opportunity cost* surrogation scores, however, we find that the difference between multiple-measure-compensation participants (mean = 0.28) and single-measure-compensation participants (mean = 0.40) is marginally significant ($t = 1.35$, $p = 0.09$). Thus, results holding the modification-package pairings constant across conditions provide additional support for H2.

Supplementary Analyses

As a follow-up analysis, we compare the surrogation scores of participants in the fixed-wage-compensation and the multiple-measure-compensation conditions. To serve as a relevant comparison with multiple-measure-compensation participants in this analysis, we calculate the fixed-wage-compensation condition surrogation scores based on modification-package choices that

TABLE 4

Comparison of Fixed-Wage and Multiple-Measure-Compensation Conditions

Low Opportunity Cost	0.00	0.02	ns
High Opportunity Cost	0.13	1.70	0.10

---

[a] This represents compensation tied directly to social-ability measures of the creatures initially designed by participants. We manipulated this source of compensation at three levels: no social-ability compensation (*fixed-wage-compensation*), performance-based compensation based on a single measure of the creature's social abilities (*single-measure-compensation*), and performance-based compensation based on three of the four measures of the creature's social abilities (*multiple-measure-compensation*). In the fixed-wage-compensation condition, participants received $10 regardless of the state of their creature's social-ability measures. In the single-measure-compensation condition, participants received $2 per level of their creature's *sing* measure (e.g., a level 4 *sing* measure resulted in compensation of $8). In the multiple-measure-compensation condition, participants received $1 per level of their creature's *sing*, *dance*, and *charm* measures (e.g., a creature with *sing* level 3, *dance* level 2, and *charm* level 5 resulted in compensation of $10).

[b] *Comprehensive* surrogation scores in this table are the percentage of participants' modification-package choices that are consistent with surrogation with *sing*, *dance*, and *charm*.

[c] *No Opportunity Cost* surrogation scores in this table are the percentage of participants' modification-package choices that are consistent with surrogation with *sing*, *dance*, and *charm* when the total of all four social-ability measure levels does not differ between modification packages.

[d] *Opportunity Cost* surrogation scores in this table are the percentage of participants' modification-package choices consistent with surrogation with *sing*, *dance*, and *charm* given that such a choice means forgoing a higher total level of the four social-ability measures.

[e] To compare surrogation with *sing*, *dance*, and *charm* between the fixed-wage-compensation and multiple-measure-compensation conditions, the surrogation scores for the fixed-wage-compensation condition in this table are based on surrogation with *sing*, *dance*, and *charm.*

[f] All p-values are presented on a two-tailed basis, given the lack of directional predictions.

capture surrogation with *sing*, *dance*, and *charm* (i.e., the compensated measures in the multiple-measure-compensation condition).

Participants' mean *comprehensive* surrogation score is 0.46 in the multiple-measure-compensation condition, and is 0.40 in the fixed-wage-compensation condition (see Table 4, Panel A). As we report in Table 4, Panel B, the difference of 0.06 is not significant (t = 1.16, ns, two-tailed). This result is similar for the *no opportunity cost* surrogation score ($\text{mean}_{\text{fixed-wage}}$ =

0.63; $\text{mean}_{\text{multiple}} = 0.63$; $t = 0.02$, ns, two-tailed). With respect to the *opportunity cost* surrogation score, the difference between the fixed-wage-compensation condition (mean = 0.16) and the multiple-measure-compensation condition (mean = 0.29) is marginally significant ($t = 1.70$, $p = 0.10$, two-tailed). These findings are consistent with the primary tests of H2, where both the *comprehensive* and *no opportunity cost* surrogation scores decreased when going from single- to multiple-measure-compensation, but the *opportunity cost* surrogation score did not reflect a significant decrease.

To further explore the surrogation phenomenon, we investigate participants' responses to a post-experimental question eliciting their allocation of attention among the four measures of sociability while making modification-package choices. Similar to the manipulation-check question regarding the creature-design task described earlier, we asked each participant to "indicate how much attention you gave to the [*sing*, *dance*, *charm*, and *pose*] abilities, by allocating 100 points among the four abilities, [allocating] more points to abilities to which you gave more attention" when making their modification-package selections. Our findings, reported in Table 5, suggest that single-measure-compensation participants allocated more attention to the *sing* measure when they selected modification packages than did fixed-wage-compensation participants (mean = 23.7 percent) ($t = 2.52$, $p < 0.01$). Importantly, multiple-measure-compensation participants *did not* allocate significantly more points to the *sing*, *dance*, and *charm* measures (mean = 83.7 percent) than did the fixed-wage-compensation participants (mean 80.0 percent) ($t = 1.57$, ns, two-tailed). This latter finding is particularly notable given evidence reported earlier that participants in the multiple-measure-compensation condition reported allocating *more* attention to the *sing*, *dance*, and *charm* measures than fixed-wage-compensation participants during the initial creature-design task, for which multiple-measure-compensation participants earned incentive compensation. This suggests that while participants in the multiple-measures-compensation setting responded in a wealth-maximizing manner to their incentives in the creature-design task, these incentives did not lead to a significant increase in surrogation for these participants.

Follow-Up Experiment

As discussed earlier, an important aspect of the internal validity of our main experiment relates to our choice not to compensate participants for their modification-package selections. While appropriate for our research purpose, this choice raises questions related to external validity. Therefore, we ran a follow-up experiment to help address this question. Specifically, we investigate whether our results hold if participants are compensated for their modification-package selections.

Our follow-up experiment was identical to our main experiment, with three exceptions. First, the follow-up experiment was 1 × 2, focusing only on the single-measure-compensation and the multiple-measure-compensation conditions, in which we expected surrogation to be most prevalent. Second, participants earned compensation for their modification-package selections. We informed participants that this additional compensation would be based on their ability to implement the strategy, and that this compensation would be determined in a similar manner to the compensation that participants earned for their creature's ability to achieve global domination. Specifically, each participant's performance during the modification-package selection task was compared to that of nine other randomly selected participants within the same experimental condition. The best performer within each ten-person group received $20, the next best performer received $18, etc. Third, we added a post-experimental question assessing participants' understanding of the compensation they earned for their modification-package selections. Participants answered a multiple choice question indicating whether their compensation for their modification-package selections was determined "Based on [their] ability to implement the strategy," "Based on [their] ability to maximize *sing*," or "Based on [their] ability to maximize *sing*, *dance*, and *charm*."

TABLE 5

Modification-Package Choice Point Allocations

Panel A: Mean Modification-Package Choice Point Allocations[a] (Standard Deviation)

Social-Ability Measures	Compensation Condition[b] Fixed-Wage Compensation (n = 27)	Single-Measure Compensation (n = 26)	Multiple-Measure Compensation (n = 26)
Sing	23.7 (6.4)	33.5 (19.2)	22.2 (10.3)
Dance	24.3 (7.6)	18.6 (8.7)	23.0 (13.7)
Charm	32.0 (14.1)	33.5 (20.5)	38.5 (24.8)
Pose	20.4 (7.7)	14.4 (9.0)	16.3 (9.4)

Panel B: Statistical Tests

	Estimate	t	p-value[c]
Points Allocated to *sing*: Fixed-Wage versus Single-Measure Compensation	9.8	2.52	< 0.01
Points Allocated to *sing*, *dance*, and *charm*: Fixed-Wage versus Multiple-Measure Compensation	3.7	1.57	ns

---

[a] *Modification-Package Choice Point Allocations* represent participants' allocations of exactly 100 points across the four social-ability measures—*sing*, *dance*, *charm*, and *pose*—when asked to "indicate how much attention you gave to the [*sing*, *dance*, *charm*, and *pose*] abilities, by allocating 100 points among the four abilities, [allocating] more points to abilities to which you gave more attention" when making modification-package selections.

[b] This represents compensation tied directly to social-ability measures of the creatures initially designed by participants. We manipulated this source of compensation at three levels: no social-ability compensation (*fixed-wage-compensation*), performance-based compensation based on a single measure of the creature's social abilities (*single-measure-compensation*), and performance-based compensation based on three of the four measures of the creature's social abilities (*multiple-measure-compensation*). In the fixed-wage-compensation condition, participants received $10 regardless of the state of their creature's social-ability measures. In the single-measure-compensation condition, participants received $2 per level of their creature's *sing* measure (e.g., a level 4 *sing* measure resulted in compensation of $8). In the multiple-measure-compensation condition, participants received $1 per level of their creature's *sing*, *dance*, and *charm* measures (e.g., a creature with *sing* level 3, *dance* level 2, and *charm* level 5 resulted in compensation of $10).

[c] All p-values are presented on a one-tailed basis, except for comparisons involving the fixed-wage-compensation and multiple-measure-compensation conditions, which are presented on a two-tailed basis.

Table 6 presents the results of the additional experiment. As shown in Panel A, participants' mean *comprehensive* surrogation score is 0.61 (n = 24) in the single-measure-compensation condition, but is only 0.46 (n = 26) in the multiple-measure-compensation condition. As we report in Panel B, the difference of 0.15 is statistically significant ($t = 2.31$, $p < 0.01$). These results are robust when considering the *no opportunity cost* surrogation score ($\text{mean}_{\text{single}} = 0.84$; $\text{mean}_{\text{multiple}} = 0.66$; $t = 2.70$, $p < 0.01$). When considering the *opportunity cost* surrogation score, the difference between conditions is marginally significant ($\text{mean}_{\text{single}} = 0.38$; $\text{mean}_{\text{multiple}} = 0.25$; $t = 1.35$, $p = 0.09$). When we drop from our analyses six participants who incorrectly answered the question in the post-experimental questionnaire about the basis of their modification-package-selection

TABLE 6

Additional Experiment

---

[a] This represents compensation tied directly to social-ability measures of the creatures initially designed by participants. We manipulated this source of compensation at two levels: performance-based compensation based on a single measure of the creature's social abilities (*single-measure-compensation*) and performance-based compensation based on three of the four measures of the creature's social abilities (*multiple-measure-compensation*). In the single-measure-compensation condition, participants received $2 per level of their creature's *sing* measure (e.g., a level 4 *sing* measure resulted in compensation of $8). In the multiple-measure-compensation condition, participants received $1 per level of their creature's *sing*, *dance*, and *charm* measures (e.g., a creature with *sing* level 3, *dance* level 2, and *charm* level 5 resulted in compensation of $10).

[b] *Comprehensive* surrogation scores are the percentage of participants' modification-package choices that are consistent with surrogation with *sing* or with *sing*, *dance*, and *charm*, depending on the compensation condition.

[c] *No Opportunity Cost* surrogation scores are the percentage of participants' modification-package choices that are consistent with surrogation with *sing* or with *sing*, *dance*, and *charm*, depending on the compensation condition, when the total of all four social-ability measure levels does not differ between modification packages.

[d] *Opportunity Cost* surrogation scores are the percentage of participants' modification-package choices consistent with surrogation with *sing* or with *sing*, *dance*, and *charm*, depending on the compensation condition, given that such a choice means forgoing a higher total level of the four social-ability measures.

[e] All p-values are presented on a one-tailed basis, given the directional predictions implied by our theory.

compensation, all results are inferentially identical, except that the *opportunity cost* results become more significant ($t = 2.14$, $p = 0.02$). These results support our theory and corroborate the findings from our main experiment.

V. CONCLUSION

This paper investigates the influence of incentive compensation on managers' propensity to use compensated measures as surrogates for strategic constructs. Our findings suggest that compensating managers based on a single measure of a strategic construct increases their propensity to use the compensated measure as a surrogate for the construct. Our results further suggest that this propensity to use compensated measures as surrogates for strategy is less pronounced when compensating managers on multiple measures of a strategic construct. Our paper contributes to a variety of research streams, including literature on firms' use of strategic performance measurement systems. Specifically, we highlight managers' tendency to use measures as surrogates for strategic constructs as a potentially detrimental response to performance measure information. Additionally, our study helps develop academic and practitioner understanding of factors that influence the extent to which firms incur this potential cost. Thus, our study is important to practicing managers and management accountants responsible for developing and implementing strategic performance measurement systems.

Notably, by finding support for both of our hypotheses, we are able to rule out a number of alternative explanations for our findings. For instance, some participants may have been confused by the incomplete compensation contracts, and believed that compensated measures were more important to their creature's ability to socialize. Such a belief would lead participants to make modification-package selections consistent with, but not driven by, surrogation. Another potential alternative explanation for results consistent with H1 is that some participants may have simply tried to make modification-package-pairing selections that were consistent with their behavior in the creature design task (Abelson et al. 1968). Motivated reasoning (Kunda 1990; Tayler 2010; Luft et al. 2011) and other psychology-based theories could also explain H1 results. Participants might identify reasons why surrogation-consistent modification packages, which also happen to be consistent with participants' emphasis when designing their creature, are superior. However, these alternative explanations cannot explain the full pattern of our findings. In particular, because they would predict high surrogation across both incentive compensation conditions, they cannot explain the increased surrogation of the strategic construct when compensation is tied to a single measure, and the *decreased* surrogation of the strategic construct when compensation is tied to multiple measures.

Our paper is subject to multiple limitations. First, while we view the rich, but non-business oriented setting as a strength of our design, the setting raises questions of boundary conditions and generalizability. For instance, we develop and test hypotheses referring to compensation based on a "single measure" or based on "multiple measures." While we operationalize these conditions using specific numbers of measures, we appreciate the continuous nature of the number of possible measures that may be included in a strategic performance measurement system. The number of measures at which surrogation begins to be mitigated is likely to depend on a variety of factors that are beyond the scope of this paper. Finally, while we draw on a vast, well-established literature relating to attention, our supplemental measures of attention are self-reported and potentially very noisy. Although we believe the goals of our study necessitate this approach, future research may benefit from utilizing more precise measures of attention.

While our focus in this paper has been the effects of compensation on strategy surrogation, future research could investigate other institutional factors that inhibit or exacerbate surrogation. Prior research identifies various measure attributes (e.g., congruence, precision, and sensitivity) that affect the optimal weighting of performance measure in the compensation contract. These attributes may also influence managers' propensity to use measures as surrogates for a strategic construct (Feltham and Xie 1994; Krishnan et al. 2005). In addition, managers' involvement in the choice of strategy may influence their propensity toward surrogation. Moreover, the extent to which surrogation is lower under multiple-measure-compensation than under single-measure-compensation may depend on the relationship among the multiple measures (e.g., extent of overlap, causal relationships). Finally, future research could explore specific implications of surrogation, such as how and under what circumstances costs of surrogation arise (e.g., managers' failure to update obsolete measures, sub-optimal strategic decisions), how the representativeness of a given measure influences the cost of surrogation with that measure, and whether strategy surrogation affects managers' evaluations of subordinates. Research addressing such issues would contribute greatly to our understanding of the surrogation phenomenon, as well as the influence of surrogation on the effectiveness of strategic performance measurement systems.

Negative Special Items and Future Earnings: Expense Transfer or Real Improvements?

ABSTRACT: Burgstahler et al. (2002) investigate the implications of special items for future earnings and report that firms use negative special items to accelerate the recognition of future expenses into the current period. That is, negative special items serve as an "inter-period transfer" device. We extend their analysis and find that earnings increase in post-special item quarters beyond the four quarters considered in Burgstahler et al. (2002). In particular, we find that future earnings increase over the subsequent 16 quarters by more than 130 percent of the reported negative special item. The earnings increases are greater for restructuring charges than for asset write-downs or goodwill impairment charges. Such patterns suggest that negative special items also signal real future performance improvements (i.e., performance improvement hypothesis) in addition to inter-period expense transfer (i.e., inter-period transfer hypothesis). Moreover, the real improvement effect appears to be driven by restructuring charges, the most prevalent type of special item.

Keywords: *negative special items; earnings management; restructuring.*

I. INTRODUCTION

Burgstahler et al. (2002; hereafter, BJS) document that negative special items (NSIs) are followed by "earnings of the *opposite sign* in subsequent quarters" (BJS 2002, 587; emphasis in the original).[1] They conjecture that NSIs, on average, represent an "inter-period transfer" of future expenses into current period income. Moreover, their empirical evidence suggests that this inter-period transfer aspect of NSIs is quite substantial, equaling over 8 percent of the original NSI for each of the first three quarters and over 27 percent of the original NSI in the fourth quarter following special item recognition. Cumulatively, their analysis suggests that over 50 percent of an NSI is realized as increased earnings in the four quarters subsequent to recognition.[2] By documenting the future earnings increases associated with NSIs, BJS present compelling evidence that earnings management in the form of inter-period expense transfer is the primary motivating factor for managers in recognizing NSIs.

We address three aspects of the BJS findings to further our understanding of inter-period expense transfer as a basis for interpreting the future earnings implications of NSIs. First, we assess the BJS inter-period transfer hypothesis by considering its implications for changes in earnings for quarters beyond the first four quarters subsequent to the recognition of the NSI. Second, we consider the implication of NSIs for changes in operating cash flows that are not a part of the BJS analyses. The cash flow aspect of our investigation is motivated by Doyle et al. (2003) who report mixed evidence regarding the relation between special items and future cash flows.[3] Third, we disaggregate NSIs into sub-types that have predictable and varying implications for future earnings and cash flows. In particular, we examine the implications for changes in future earnings and operating cash flows for the current recognition of restructuring charges, asset write-downs, and goodwill impairment charges.[4]

While expense transfer certainly constitutes one possible source of the near-term future earnings increases documented in BJS, such increases are also consistent with the notion that the underlying events and actions prompting the recognition of a special item lead to real future performance improvements by the firm. For example, take the case of a firm that undertakes a restructuring of operations (a subclass of NSIs). If the restructuring includes a workforce reduction and plant closing, then the firm may realize future efficiency gains from reduced payroll expenses and operating expenses associated with running the plant. As long as the reduced expenses exceed the decline in revenue from the lost productive capacity, the firm will realize efficiency gains. However, unlike expense transfer driven gains, such real improvement effects need not decline and may well even strengthen in quarters beyond $t+4$ relative to the special item event quarter. By evaluating the implications of NSIs for future earnings and operating cash flows, our analysis allows us to gain insight into the particular roles of expense transfer and real improvements for the future performance consequence of NSIs. Further, by separately examining the implications of restructuring charges, asset write-downs, and goodwill impairment charges, we are able to focus on NSI sub-types that are most likely to be associated with efficiency improvements, expense transfer, and no future effect, respectively.

---

[1] BJS extend prior research (e.g., Bernard and Thomas 1990; Ball and Bartov 1996) by documenting that security prices fail to fully reflect predictable elements of the relationship between current and future earnings. The primary focus of this aspect of their study concerns whether the market fully impounds the future income properties of special items. They report that prices better reflect the future implications of special items than the other components of earnings. This finding is consistent with the notion that the implications of transitory special items for future earnings are relatively clear compared to other components of earnings.

[2] The acceleration of future expense as part of a current NSI is simply a timing issue in that future expenses taken now will not be incurred in the future periods resulting in an increase to future net income. For example, an asset write-down recognized as an NSI in the current period represents the acceleration of future depreciation expense. Thus, earnings will be higher in future periods by the amount of the NSI (i.e., the accelerated depreciation).

[3] They report an insignificant relation between special items and operating cash flows, but a significantly positive relation with free cash flow (see Doyle et al. 2003, 160–161, Tables 3 and 4). Their analysis, however, does not partition special items into negative and positive amounts, whereas our entire focus is on the distinct impact of NSIs documented in BJS.

[4] We predict that restructurings will lead to efficiency improvements, asset write-downs are associated with expense transfer, and goodwill impairment charges will not be associated with efficiency gains or expense transfer. We discuss this in more detail later in the text.

An accrual-based income-transfer to *increase* current income borrows against future earnings by either deferring the recognition of expenses or accelerating the recognition of revenue. In contrast, NSI-based expense transfer *decreases* current income, thus transferring earnings to the future by accelerating the recognition of future expense. The result is lower current period earnings and higher future period earnings (BJS). This effect is naturally bounded by the amount of the special item, is inherently non-sustainable in perpetuity, and must at some point dissipate.[5] As time passes and the transfer effect declines, there is a necessary reversal in income *changes* since within each earnings difference, the expense transfer effect in the form of an increase in earnings is greater in the earlier earnings number than in the subsequent earnings number.[6] In this respect, the empirical implications of the expense-transfer hypothesis resemble the well-known future income reversal properties of accruals.[7] Hence, as is true for accrual-based earnings increases, NSI expense transfer will lead to expected income change declines in future periods as the aggregate amount of the transfer is consumed.

Our initial tests of the expense-transfer hypothesis center on determining whether any evidence of these predicted declines in the transfer effect exists in quarters $t+5$ through $t+16$ relative to the NSI event in quarter t. We find no evidence of these expected declines and, in fact, we find considerable evidence supportive of the proposition that NSIs in quarter t imply increases in income in quarters $t+5$ through $t+16$. Similar to the Francis et al. (1996) suggestion that positive price responses to restructuring charge announcements (one type of special item) signal improvements in future performance, we interpret this persistent income effect as evidence that NSIs in part reflect structural improvements in operations/strategy that favorably impact long-term profitability.[8]

Our interpretation of these patterns of post-NSI income increases is conditioned on the assumption that expense transfer effects must decline over time, which is necessarily true given a sufficiently long time horizon. However, it is possible that our horizon of 16 quarters is not sufficiently long enough to capture this necessary decline. Thus, an alternative explanation for our results is that the amount of the expense transfer is increasing over our 16 quarter time horizon rather than declining. For example, a firm that recognizes a $1,000 NSI in quarter t may be transferring future expense of \$100 from year +1, \$200 from year +2, \$300 from year +3 and \$400 from year +1. To address this possibility, we also investigate the relation between quarter *t* NSIs and future changes in operating cash flows. Since cash flows are less susceptible to manipulation (Doyle et al. 2003), NSI-induced increases in operating cash flows are more consistent with efficiency gains than expense transfer.

---

[5] BJS report that more than 50 percent of the initial special item is transferred in the form of increased year +1 income; therefore, it follows that either this effect must decline in magnitude or it will naturally be exhausted in year +2.

[6] Figure 2, which we discuss in greater detail later in the text, demonstrates the effect of expense transfer on future earnings under the various expense transfer assumptions (i.e., declining, constant, and increasing) using a simple earnings expectation model.

[7] That is, when a period t accrual manipulation is used to increase period t income, a decline is predicted for income in period $t+1$ relative to period t (Kang and Sivaramakrishnan 1995; Sloan 1996). This decline occurs, in part, because future period income has been borrowed and must eventually be paid back. However, it also occurs because any accrual-driven manipulation of income in period t is inherently transitory. Hence, even if the borrowed earnings are replaced by borrowing again in period $t+1$, the expected income change remains negative unless one assumes that the borrowing can increase indefinitely over time, a notion inconsistent with Barton and Simko (2002).

[8] McVay (2006) documents that earnings are unusually low in special items quarters. Thus, an alternative explanation is that our results simply reflect the mean reversion in earnings over time. However, we do not believe that mean reversion explains these results. As discussed in the "Sensitivity Analyses" section, we specifically address this issue by controlling for prior firm performance. Our conclusions are robust to the inclusion of this additional control.

Overall, we find that NSI-induced earnings increases over the subsequent 16 quarters represent over 130 percent of the original charge.[9] Pure expense transfer naturally cannot exceed 100 percent of the amount of the NSI, so any cumulative effect over 100 percent cannot be the result of expense transfer alone. On average, it seems probable that most NSIs reflect current activity and are of a non-transferable nature (i.e., real costs related to current special item activity or classification shifting).[10] Thus, it is unlikely that inter-period expense transfer can plausibly account for the majority of the NSI-induced future earnings increases we document. For example, if a current NSI of \$1.00 consists of \$0.50 expense transfer, \$0.25 classification shifting, and \$0.25 true NSI current costs, then expense transfer is actually bounded at 50 percent of the NSI charge. Consistent with this conjecture, further empirical evidence suggests that NSIs result in substantial future efficiency gains. Examining the relation between NSIs and future operating cash flows, we find that almost a third of the special items-induced earnings increases are realized in the form of increases in operating cash flow.

We next examine three NSI sub-types, restructuring charges, asset write-downs, and goodwill impairment charges, which we predict as having differing implications for future earnings and operating cash flows. To the extent that NSIs are associated with future efficiency gains, we expect that restructuring charges will most likely lead to real improvements. On the other hand, we expect asset write-downs to be most closely associated with the type of charge that represents an acceleration of future expense (i.e., expense transfer) as an asset write-down is usually the acceleration of depreciation expense. We do not expect goodwill impairment charges to be associated with future earnings or operating cash flows.

Our results are generally consistent with these expectations. We find that restructuring charge-induced earnings (operating cash flow) increases accumulated over the subsequent 16 quarters represent over 500 (150) percent of the original NSI. In contrast, goodwill impairment charges have little empirical relation to future earnings or operating cash flows. With respect to asset write-downs, we find that future earnings (operating cash flow) increases following the asset write-down are less than one-third (half) of the corresponding amount that we find for restructuring charges. Taken together, our evidence suggests that expense transfer provides only a partial explanation for the BJS results. Real improvements in future profitability, especially those related to restructuring charges, appear to be at least as important as the expense transfer effects in explaining the BJS results.

Section II presents the base models for the BJS replication analysis and addresses the predictable future earnings implications of the expense-transfer hypothesis and the real improvements hypothesis. Section III details the sample selection and descriptive statistics. Section IV presents the BJS replication results and the results from further tests of the inter-period expense-transfer hypothesis and the real improvements hypothesis. Section V briefly summarizes and concludes.

---

[9] The cumulative effect is subject to measurement error but follows directly from the BJS analysis. We attempt to avoid overstating the effect by measuring pre-tax earnings and special items as well as controlling for serial reporting of special items in sensitivity analyses discussed later.

[10] True current NSI activities can include such items as termination benefits for terminated employees or plant closing costs. Classification shifting occurs when firms report a recurring operating cost as part of an NSI (McVay 2006; Fan et al. 2010).

II. INTER-PERIOD EXPENSE TRANSFER VERSUS REAL IMPROVEMENTS

The BJS analysis focuses on the following equation for $k = 1,\ldots,4$:[11]

$$(E_{i,t+k} - E_{i,t+k-4}) = b_{0k} + b_{1k}NSI_{i,t} + b_{2k}(E_{i,t} - NSI_{i,t} - E_{i,t-4}) + e_{i,t}, \tag{1}$$

where:

$E_{i,t+k}$ = income before extraordinary items (Compustat data item IBQ) for firm i in quarter $t+k$ (where $k = 1,\ldots,4$) divided by the market value of equity (MKVALTQ) in quarter $t-4$; and

$NSI_{i,t}$ = negative special items (SPIQ) for firm i in quarter t multiplied by 1 minus the top federal statutory tax rate divided by the market value of equity (MKVALTQ) in quarter $t-4$.

Equation (1) is based directly on the BJS analysis. The dependent measure in Equation (1) ($E_{i,t+k} - E_{i,t+k-4}$), the seasonal change in earnings for quarters $t+1$, $t+2$, $t+3$, and $t+4$ is incorporated in this model because it provides a way to test the effect of current NSIs and earnings before NSIs ($E_{i,t} - NSI_{i,t} - E_{i,t-4}$) on future earnings. That is, if there is a relationship between future earnings and NSIs, then the dependent measure in Equation (1) should capture that effect. This general notion also holds true for each of the dependent measures incorporated in all of the regression models in this study. BJS report that the coefficients on NSIs are significantly negative at lags 1, 2, and 3, and the coefficient at lag 4 is significantly less than −1. Taken together, BJS report evidence that suggests over 50 percent of the original NSI is recovered through increased earnings in the four subsequent quarters. BJS (2002, 598) conclude that their evidence is consistent with NSIs representing the "current recognition of expenses that would otherwise have been recognized in subsequent quarters, thereby decreasing income in quarter t and increasing income in subsequent quarters." An alternative explanation is that NSIs represent some combination of inter-period expense transfer and operational changes that result in real improvements to future performance.

Future Period Implications of the Expense-Transfer Hypothesis

The initial portion of our analysis addresses the empirical implications of the expense-transfer hypothesis for earnings changes beyond quarter $t+4$. In a simple two-year setting where quarters $t+1$ to $t+4$ correspond to the first four post-special item quarters (i.e., year +1) and quarters $t+5$ to $t+8$ correspond to the fifth through eighth post-special item quarters (i.e., year +2), expense transfer over this two-year period must take on one of three distinct forms: (1) *declining*—the earnings increase from expense transfer in year +2 is less than year +1; (2) *constant*— the earnings increase from expense transfer in year +2 is equal to year +1; or (3) *increasing*— the earnings increase from expense transfer in year +2 is greater than year +1. The specific implications for the NSI coefficient in Equation (1) of these transfer effects depends on two factors: (1) whether the lag between the independent and dependent earnings change is four quarters or fewer than four quarters (i.e., an interim quarter lag such as when the change in quarter t earnings is explained by the change in quarter $t-1$ earnings); and (2) whether the independent earnings change measure "straddles"[12] the *NSI* event quarter t (e.g., $E_{t+3} - E_{t-1}$) or reflects changes entirely based on post-special-items-event earnings (e.g., $E_{t+5} - E_{t+1}$).

---

[11] This equation is a modified version of that in BJS. BJS focus on both positive and negative special items. We report descriptive statistics for all observations, but our main analyses focus solely on NSIs as positive special items are mainly transitory and do not exhibit the reversal properties of interest in this study or that of BJS. Results of all tests with positive special items are available on request.

[12] That is, the later earnings number in the change is for a post-special-item quarter while the earlier earnings number is for a pre-special-items quarter. Earnings for quarter $t+2$ less earnings for quarter $t-2$, where quarter t is the special item event quarter is an example of a straddle.

If the expense transfer is declining, then the transfer effect increases both components of post-special-items event dependent earnings changes (i.e., E_{t+k} and E_{t+k-4}). However, the transfer amount is greater in the earlier (E_{t+k-4}) earnings number than the later (E_{t+k}) earnings number. Earnings differences that do not straddle the special item quarter will be negative since the later earnings number has less transfer than the earlier earnings number (i.e., we expect that $E_{t+k} < E_{t+k-4}$). Thus, the declining transfer assumption predicts positive coefficients on *NSI* in Equation (1) beyond the straddle period. If the expense transfer is increasing, then earnings differences will be positive since the transfer amount is greater in the later (E_{t+k}) earnings number than the earlier (E_{t+k-4}) earnings number. Thus, the increasing transfer assumption predicts negative coefficients on *NSI* in Equation (1) for all periods. Beyond the straddle period, the constant transfer assumption predicts zero coefficients on *NSI* as the early and late transfer effects are equal in amount.[13]

Figure 1 summarizes the *NSI* coefficient predictions under the declining, constant, or increasing transfer patterns and Figure 2 illustrates the effect of each transfer pattern assumption for a simple earnings expectations model. Figure 2 shows that unless the transfer amounts are very small, the transfer will become exhausted very rapidly as it is necessarily bounded by the amount of the charge.[14]

Implications of the Real Improvements Hypothesis

While evidence of NSI-induced earnings increases beyond quarter $t+4$ is consistent with *increasing* special items expense transfer, it is also consistent with a very different perspective of the post-NSI income increases reported in BJS. Specifically, such increases potentially reflect the realization of future efficiency, operating, or strategic improvements that are either consequences of, or signaled by, NSIs. Moreover, it is possible for the income effects of such improvements to increase over time. Thus, while a pattern of steadily increasing income could be explained as an increasing expense transfer pattern, real improvements appear to provide a more plausible explanation. Conversely, a pattern of decreasing future income would appear to be better explained by declining expense transfer than by real changes in performance.

Additional Tests of Expense Transfer versus Real Improvements

Because future income patterns cannot completely resolve the question of whether and to what extent NSIs represent expense transfer versus real improvements, we conduct three additional empirical analyses to examine this issue further. We examine (1) the total earnings increases over the subsequent 16 quarters related to NSIs; (2) the extent to which NSIs influence future changes in operating cash flows; and (3) the total earnings and operating cash flow increases over the subsequent 16 quarters related to restructuring charges, asset write-downs, and goodwill impairment charges.

Given that NSI-induced expense transfer is bounded by the amount of the NSI, evidence that the total earnings increase related to NSIs exceeds 100 percent of the original NSI would suggest that NSIs lead to some level of real improvements. Hence, we estimate the cumulative transfer effect as reflected in earnings changes over the four years following the special item and compare this total to the 100 percent baseline. While the cumulative effect evaluation appears to address a

---

[13] Prior drafts of this manuscript include an appendix containing a rigorous evaluation of all possible coefficient predictions under each of the transfer assumptions. This appendix, omitted for space constraints, is available from the authors upon request.

[14] For example, if a depreciable asset is written down and the asset has a remaining useful life of 15 years, the future depreciation transferred into the current NSI (i.e., the amount of the write-down) will not be completely exhausted until the asset is fully depreciated (i.e., 15 years from the current period).

FIGURE 1
Summary Predictions for Sign of Negative Special Items Coefficients in Future Earnings Regressions beyond Quarter *t*+4

	Inter-Period Expense-Transfer Hypothesis					
	Straddle Explanatory Earnings Changes[a]			**Post-Special-Item Period Explanatory Earnings Change**[b]		
Earnings Lag	**Declining**[c]	**Constant**[d]	**Increasing**[e]	**Declining**[c]	**Constant**[d]	**Increasing**[e]
Lag 4	?	–	–	+	0	–
Lag 1,2, & 3	+	+	–	+	0	–

All predictions in Figure 1 are with respect to the coefficient b_1 in the following equation:

$$(PTI_{i,t+k} - PTI_{i,t+k-4}) = b_{0(t+k,l)} + b_{1(t+k,l)}RNSI_{i,t} + b_{2(t+k,l)}(PTI_{t+k-l} - PTI_{t+k-l-4}) + e_{i,(t+k,l)},\ t+k > t+4.$$

$PTI_{i,t+k}$ is pre-tax income for firm *i* in quarter *t*+*k* divided by the market value of equity in quarter *t*–4; *l* is an index variable that equals 1, 2, 3, or 4 and reflects the lag in quarters between the dependent and independent earnings changes.

$RNSI_t$ is reported negative special items recognized in quarter *t* divided by market value of equity in quarter *t*–4.

[a] A "straddle" earnings change quarter occurs when the later earnings number in the earnings change is for a post-special-item quarter while the earlier earnings number is for a pre-special-items quarter.

[b] A post-special-items change quarter occurs when both earnings measures are values that occur after the NSI quarter.

[c] For a "declining" special items transfer, the amount of future income recognized as a negative special item in quarter *t* declines, on average, in (seasonal) amount over the time horizon examined. That is, the special item transfer benefits earlier future period income more than later future period income.

[d] A "constant" special items transfer is constant in (seasonal) amount in each quarter over the time horizon examined.

[e] An "increasing" special items transfer increases in (seasonal) amount over the time horizon examined.

sufficient condition for the presence of at least some level of real improvement in the post-special-item earnings changes, there are two issues with respect to this analysis. First, this analysis provides only a floor for measuring the extent of NSI-induced real improvements (i.e., the degree to which earnings increases exceed 100 percent of the NSI). Second, our measure of NSI-induced earnings increases is subject to measurement error. To address both of these potential design limitations, we investigate an additional measure that is more amenable to such inferences: changes in future operating cash flows. Operating cash flows are less susceptible to manipulation by management and, thus, NSI-induced increases in operating cash flows are more likely a result of efficiency gains than expense transfer.

Finally, special items are quite heterogeneous and various sub-types of special items have differing implications for future earnings and operating cash flows. Operational restructurings are generally undertaken to create future efficiency gains (Brickley and Van Drunen 1990; Atiase et al. 2004; Clement et al. 2007). However, prior research and anecdotal evidence also suggests that restructuring charges and related reversals may be associated with earnings management activity

---

[a] The "declining transfer assumption" is consistent with a depreciable asset write-down where the asset is depreciated under the accelerated method of depreciation. The "constant transfer assumption" is consistent with a depreciable asset write-down where the asset is depreciated under the straight-line method of depreciation. We have no clear example of an NSI that fits the "increasing transfer assumption." That said, the "increasing transfer assumption" implies more expense is transferred from later in time quarters than quarters immediately adjacent to the NSI quarter.

[b] The quarter t innovation is the reported NSI.

[c] For example, under the declining transfer assumption the expected seasonally differenced earnings for quarter t+4 of $1.15 is the $10.15 earnings for quarter t+4 less the $9.00 earnings for quarter t.

(e.g., Smith and Lipin 1996; Levitt 1998; Moehrle 2002; Bens and Johnson 2009). Thus, changes in earnings induced by restructuring charges may potentially reflect real improvements or expense transfer. On the other hand, future changes in cash flows that result from restructuring activity will more likely be associated with real improvements since cash flows are less susceptible to intertemporal transfer.

Statement of Financial Accounting Standards 121 (SFAS 121), *Accounting for the Impairment of Long-Lived Assets*, indicates that an asset impairment exists if the asset's recoverable cost is lower than the book value of the asset. In this case, a firm must write the asset down to its fair market value. When a long-lived asset is written down to fair market value, the accounting effect of this event is to transfer future depreciation expense into to the current period as a special item. Unless an asset write-down is taken in conjunction with some other charge or event, the only effect a write-down can have is to transfer depreciation expense from the future into the current period. Consistent with other concurrent events being recognized with asset write-downs, Rees et al. (1996) report that firms with asset write-downs also record significant unexpected accruals in the year of the write-down. However, they also find that these unexpected accruals do not reverse in subsequent periods. Thus, our expectation is that when the NSI is an asset write-down, the most likely result will be pure NSI expense transfer.

The Financial Accounting Standards Board adoption of Statement of Financial Accounting Standards 142 (SFAS 142), *Goodwill and Other Intangible Assets*, in June of 2001 fundamentally changed the accounting for goodwill. Prior to the adoption of SFAS 142, goodwill was recognized as an asset and amortized over a period of not more than 40 years. However, SFAS 142 eliminated goodwill amortization. Under current rules, goodwill impairment is merely the write-off of the value of goodwill when its fair value is determined to be less than fair market value.

Since goodwill is not amortized, an impairment of goodwill does not accelerate future expense recognition. However, goodwill impairment implies lower future cash flows that necessitate recognition of the goodwill impairment charge. Thus, our expectation is that goodwill impairment charges will have little relation to future earnings, but may be associated with lower future cash flows. However, if goodwill impairment signals a change in the firm's future operational or strategic direction that will affect the value of goodwill, the charge may be associated with future performance improvements. Taken together, the expectation is that there will be no future earnings and lower cash flow effects from the impairment of goodwill. By investigating the relationship of the cumulative restructuring charge, asset write-down, and goodwill impairment effects on future earnings and operating cash flows, we can assess the extent of expense transfer versus real improvements via these special item sub-types that we predict will have real improvement, expense transfer, and zero transfer implications, respectively.

III. SAMPLE SELECTION AND DESCRIPTIVE STATISTICS

Our sample consists of quarterly earnings data from 2002–2009 drawn from Compustat quarterly data files. We eliminate observations using the same criteria as that applied by BJS (2002, 594).[15] We begin with a sample of 260,874 quarterly observations with non-missing earnings before extraordinary items (IBQ) and non-missing special items (SPIQ). We eliminate quarterly observations missing market value of equity (MKVALTQ) at quarter t–4. In addition, we eliminate observations (1) that do not have a minimum of nine contiguous quarters of earnings surrounding quarter t; and (2) where the absolute value of earnings for quarters t–4 to t+4 exceeds the market value of equity at t–4.[16] Our data requirements and sample selection criteria, summarized in Panel A of Table 1, result in a test sample of 163,628 firm-quarter observations (9,234 firms).

Panel B of Table 1 reports the frequencies of special items observations by quarter for the final sample of 163,628 observations. The data in this table show, consistent with BJS, a larger proportion of negative to positive special items (36,609 versus 13,252). We also find that the reporting of special items is relatively stable across the interim quarters (1–3); however, in the fourth quarter, the percentage of non-zero special items increases significantly relative to the interim quarters. In the fourth quarter, 30.9 and 10.2 percent of all observations report negative and positive special items, respectively. In the interim quarters, the average percentages are 19.8 and 7.5 percent, respectively. Panel B of Table 1 also reports the mean pre-tax special item scaled by the quarter t–4 market value of equity. Positive special items remain relatively stable across all quarters, but NSIs appear to be larger in the fourth quarter relative to interim quarters. In the fourth quarter, the mean scaled *NSI* is –0.036, while it ranges from –0.015 to –0.022 for the three interim quarters. Overall, these sample descriptive statistics are very similar to those reported by BJS.

Panel C of Table 1 reports mean market value of equity, pre-tax special items, pre-tax income, and operating cash flows. We report pre-tax income and operating cash flows for the year prior to the special item recognition as well as the four years subsequent to the special item recognition. Our evidence suggests that special item firms are larger than firms that do not recognize special items.

---

[15] We incorporate the same sample selection criteria as BJS except their elimination of immaterial (less than 1 percent of market value) NSIs. For robustness, we rerun all of our tests excluding immaterial NSIs. All results are quantitatively and qualitatively unchanged.

[16] We apply these criteria to both income before extraordinary items and pre-tax income. BJS include only income before extraordinary items in their study.

TABLE 1

Sample Selection Criteria and Descriptive Statistics

---

[a] The mean pre-tax SI reported here is calculated as the reported special item in quarter t scaled by the market value of equity in quarter t–4.

[b] The observations for this table are further reduced from Panel B by absolute values of PTI_{t+k} and CFO_{t+k}, where $k = 1$ through 16, greater than 1.

[c] Reported special items in quarter t are equal to, less than, or greater than zero, respectively.

Variable Definitions:
$MVAL_{i,t-4}$ = market value of equity (Compustat data item MVALTQ) for firm i in quarter t–4;
$PTI_{i,t+k}$ = pre-tax income (PIQ) for firm i in quarter $t+k$ (where $k = 1,\ldots,16$) divided by the market value of equity (MKVALTQ) in quarter t–4;
$CFO_{i,t+k}$ = cash flow from operating activities (OANCFQ) for firm i in quarter $t+k$ (where $k = 1,\ldots,16$) divided by the market value of equity (MKVALTQ) in quarter t–4;
$\Sigma 4QPTI_{i,y} = (PTI_{i,t+k} - PTI_{i,t+k-4})$ summed for the four quarters where k equals $1,\ldots,4$ for $y = 1$; $5,\ldots,8$ for $y = 2$; $9,\ldots,12$ for $y = 3$; and $13,\ldots,16$ for $y = 4$; and
$\Sigma 4QCFO_{i,y} = (CFO_{i,t+k} - CFO_{i,t+k-4})$ summed for the four quarters where k equals $1,\ldots,4$ for $y = 1$; $5,\ldots,8$ for $y = 2$; $9,\ldots,12$ for $y = 3$; and $13,\ldots,16$ for $y = 4$.

We find that the mean market value of equity for negative and positive special item firms is \$5.4 and \$4.4 billion, respectively. Both are much larger than the mean market value of equity for zero-special item firms of \$2.0 billion.

On average, sample firms report increasing pre-tax income and operating cash flows as indicated by the generally positive values on $\Sigma 4QPTI_{i,y}$ and $\Sigma 4QCFO_{i,y}$. $\Sigma 4QPTI_{i,y}$ and $\Sigma 4QCFO_{i,y}$ are year-by-year, four-quarter summations of the seasonal differences in earnings and operating cash flows, respectively. However, it appears that the increases in $\Sigma 4QPTI_{i,y}$ and $\Sigma 4QCFO_{i,y}$ are most pronounced for NSI firms. In particular, we find that $\Sigma 4QPTI_{i,y}$ ($\Sigma 4QCFO_{i,y}$) increases for NSI firms from –0.036 (0.054) in the year prior to recognition to 0.049 (0.144) in the fourth year subsequent to the special item quarter. For zero special items firms, we find that $\Sigma 4QPTI_{i,y}$ ($\Sigma 4QCFO_{i,y}$) increases from –0.004 (0.063) in the year prior to the current quarter to 0.045 (0.128) in the fourth year subsequent to the current quarter. Overall, we find that the change in $\Sigma 4QPTI_{i,y}$ ($\Sigma 4QCFO_{i,y}$) for negative, positive, and zero special item firms from year -1 to year +4 is 0.085 (0.090), 0.004 (0.072), and 0.049 (0.065), respectively. Thus, our descriptive evidence suggests that NSI firms, on average, show improvements in performance substantially greater than positive or zero special item firms in the four years subsequent to recognition.

IV. EMPIRICAL RESULTS

Replication of BJS

We begin our analysis with a replication of the BJS earnings persistence regressions, estimating the coefficient relating seasonally differenced earnings to subsequent values of seasonally differenced earnings. Since the time period of our analysis differs, we replicate the BJS analysis to investigate whether the main results from their study still hold. Consistent with BJS, we estimate Equation (1) separately for quarters with positive, negative, and zero special items. However, since the focus of our investigation is NSIs, for brevity we only report the estimations for NSIs.[17]

The results from the estimation of Equation (1) are reported in Table 2. We report our results for the estimation of Equation (1) (Current Sample) as well as those reported by BJS (2002, 596, Table 2, Panel B). We find that the coefficients at all lags are negative and significant (two-tailed $p < 0.01$).[18] Moreover, the crucial fourth lag coefficient is -1.342 and significantly less than -1 (two-tailed $p < 0.01$). Overall, the results from the estimation of Equation (1) closely parallel those reported by BJS both quantitatively and qualitatively. Moreover, our Equation (1) results suggest an expense transfer of approximately 63 percent, which is consistent with the 56 percent transfer effect reported by BJS.[19]

BJS Replication with Pre-Tax Special Items

BJS adjust special items for taxes in order to enhance comparability to the after tax income numbers that serve as the foundation of Equation (1). The tax rate used to adjust special items in

---

[17] Our results with respect to positive and zero special item firms are quantitatively and qualitatively similar to those tabulated in BJS. These untabulated results are available from the authors on request.

[18] In all regression tests, the t-statistics we rely on are based on robust-standard errors using two-way clustering by firm and year to control for both time-series and cross-sectional dependence (Gow et al. 2010). We thank Ian Gow for providing us with the SAS code to perform the two-way clustering procedure.

[19] To arrive at the 63 percent expense transfer the b_{1k} coefficients are summed for $k = 1, 2, 3$, and 4 then 1 is added to this sum. Thus, we add $(-0.074) + (-0.102) + (-0.111) + (-1.342) + 1$ for a total of -0.629. Since *NSI* is a negative value in Equation (1), the summed negative coefficients imply an increase to earnings. The 56 percent for the BJS estimates is arrived at similarly.

TABLE 2

Relation between NSIs and Seasonally Adjusted Future Earnings (BJS Replication) Estimated b_{1k} and b_{2k} from Equation (1):

$$(E_{i,t+k} - E_{i,t+k-4}) = b_{0k} + b_{1k}NSI_{i,t} + b_{2k}(E_{i,t} - NSI_{i,t} - E_{t-4}) + e_{i,t}$$

*, ** Significantly different from zero at the 0.05 and 0.01 levels, respectively, in a two-tailed test.
++ Significantly different from −1 at the 0.01 level in a two-tailed test (applies only for estimates of b_1 at $k = 4$).
[a] The significance of the BJS estimates are taken from BJS (2002, Table 2, p. 596).

Variable Definitions:
$E_{i,t+k}$ = income before extraordinary items (IBQ) for firm i in quarter $t+k$ (where $k = 1, 2, 3$, or 4) divided by the market value of equity (MKVALTQ) in quarter t–4; and
$NSI_{i,t}$ = negative special items (SPIQ) for firm i in quarter t multiplied by 1 minus the statutory tax rate (35 percent) divided by the market value of equity (MKTVALTQ) in quarter t–4.

their Table 2 (p. 596) analyses is the top federal statutory rate applicable for each year of their sample. However, Beaver et al. (2006) report evidence that suggests that average effective tax rates for NSI observations are substantially less than the top statutory rate.[20] Consistent with Beaver et al. (2006), in additional testing (not tabulated), we estimate that effective tax rates for NSIs range between 3 and 14 percent. Since firm- and quarter-specific values of the true special items tax rates are unobservable, we eliminate the assumed tax rate effect on parameter estimates by performing all subsequent analyses on pre-tax income and special items.

In this section, we evaluate how using pre-tax income and NSIs affects the BJS inferences about the association between NSIs and future income changes by estimating a pre-tax version of the BJS model. In particular, we modify Equation (1) by replacing earnings before extraordinary items (*E*) with pre-tax income (*PTI*) and tax-adjusted negative special items (*NSI*) with reported (unadjusted) negative special items (*RNSI*). Specifically, we estimate the following equation for $k = 1,\ldots,4$:

$$(PTI_{i,t+k} - PTI_{i,t+k-4}) = b_{0k} + b_{1k}RNSI_{i,t} + b_{2k}(PTI_{i,t} - RNSI_{i,t} - PTI_{i,t-4}) + e_{i,t}, \tag{2}$$

where:

$PTI_{i,t+k}$ = pre-tax income (PIQ) for firm i in quarter $t+k$ (where $k = 1,\ldots,$or 4) divided by the market value of equity (MKVALTQ) in quarter t–4; and

---

[20] The lower tax rate for NSI firms documented by Beaver et al. (2006) reflects the fact that these firms are frequently loss firms as well. Beaver et al. (2006) report that in their sample, loss observations have average ETRs of 7 percent, while profit observations have average ETRs of 33.2 percent. They further report that 37 (20) percent of loss (profit) firms report an NSI.

$RNSI_{i,t}$ = pre-tax negative special items (SPIQ) for firm i in quarter t divided by the market value of equity (MKVALTQ) in quarter t–4.

We report the results of estimating Equation (2) in Table 3. For comparative purposes, we report the results from estimating Equation (1), the after-tax BJS model replication, in Table 3 as well. Based on the b_{1k} *RNSI* coefficient estimates reported in Table 3, the aggregate future period pre-tax income effect for the first four quarters following the recognition of the NSI is approximately 7.8 percent of the reported pre-tax negative special item (*RNSI*). This aggregate effect is markedly less than the 62.9 percent aggregate effect per our Table 2 estimates and the 56.4 percent effect obtained by aggregating the values reported in BJS (2002, 596, Table 2).

Particularly striking is the increase in the crucial $k = 4$ lag from -1.342 to -0.997. This increase is consistent with a true special items tax rate that is less than the top statutory tax rate used to adjust special items in Equation (1). Since the tax rate impact on coefficient estimates is of a scalar nature (Cready et al. 2011), the degree of coefficient shift increases directly with the magnitude of the underlying coefficient that is being scaled. Thus, it is not surprising that the coefficient shift is greatest for the fourth lag since the fourth quarter lag coefficient is greater in absolute value relative to the interim lags.[21] Overall, the evidence reported in Table 3 strongly supports the notion that the use of the top statutory tax rates to adjust special items introduces substantial bias into *NSI* coefficient estimates from Equation (1), consistent with the conclusions of Cready et al. (2011).[22]

Negative Special Items and Future Period Earnings Changes

Table 4 reports tests of our predictions about the relation between NSIs and future period earnings changes beyond quarter t+4. Specifically, we report the results of estimating the following regression:

$$(PTI_{i,t+k} - PTI_{i,t+k-4}) = b_{0k} + b_{1k}RNSI_{i,t} + b_{2k}(PTI_{i,t+k-l} - PTI_{i,t+k-l-4}) + e_{i,t}. \quad (3)$$

All variables are as previously defined. Table 4, Panel A reports *RNSI* coefficient estimates for those settings where the explanatory earnings change "straddles" the special item quarter. A straddle occurs when the later earnings number in the earnings change is for a post-special-item quarter, while the earlier earnings number is for a pre-special-items quarter. Earnings for quarter t+2 less earnings for quarter t–2, where quarter t is the special item event quarter, is an example of a straddle. We report these *RNSI* straddle coefficient estimates separately since, as reported in Figure 1, predictions for such straddle quarters differ somewhat from the predictions for post-special-item period explanatory earnings changes. We find negative and significant (two-tailed $p < 0.01$) *RNSI* coefficients for all ten of the straddle estimates we report in Panel A. The coefficients range in magnitude from -0.051 to -0.110. The negative coefficients for the fourth lag estimates are consistent with either increasing or constant expense transfer. On the other hand, the interim lag coefficient estimates are only consistent with increasing expense transfer.

Panel B of Table 4 reports *RNSI* coefficient estimates for those settings where the independent explanatory earnings changes are based exclusively on post-special items earnings (e.g., $PTI_{i,t+6}$ −

---

[21] For a detailed evaluation of the empirical impact of misstated tax rates on the interim and fourth lag coefficient estimates, see Cready et al. (2011).

[22] In addition to using pre-tax special items to estimate our models, we also re-estimate each of our models using special items adjusted for the top statutory rate and the firm-specific marginal tax rate. We adjust at the firm-specific marginal rate by adjusting special items for firm-specific annual marginal tax rates provided by Graham (1996a, 1996b). The results of these untabulated additional tests are quantitatively and qualitatively similar to our tabulated results using pre-tax special items. We thank John Graham for making the firm-specific marginal tax rate data available to us.

TABLE 3

Relation between Pre-Tax NSIs and Seasonally Adjusted Pre-Tax Future Earnings Estimated b_{1k} and b_{2k} from Equation (2):

$$(PTI_{i,t+k} - PTI_{i,t+k-4}) = b_{0k} + b_{1k}RNSI_{i,t} + b_{2k}(PTI_{i,t} - RNSI_{i,t} - PTI_{i,t-4}) + e_{i,t}$$

Variable Definitions:
$PTI_{i,t+k}$ = pre-tax income (PIQ) for firm *i* in quarter *t*+*k* (where $k = 1,\ldots,$or 4) divided by the market value of equity (MKVALTQ) in quarter *t*–4; and
$RNSI_{i,t}$ = pre-tax negative special items (SPIQ) for firm *i* in quarter *t* divided by the market value of equity (MKVALTQ) in quarter *t*–4.

$PTI_{i,t+2}$). The expense transfer predictions on the *RNSI* coefficients are consistent for interim and fourth lag coefficients within each form of expense transfer. That is, the declining, constant, and increasing forms of expense transfer predict positive, zero, and negative *RNSI* coefficients for both interim and fourth lag estimates, respectively. Panel B reports 38 *RNSI* coefficient estimates for quarters *t*+6 through *t*+16. Of the 38 coefficients estimates, 36 are negative and 29 of these are significant (two-tailed $p < 0.05$). Our coefficient predictions summarized in Figure 1 suggest that negative coefficients in post-special-item period explanatory quarters are indicative of an NSI in quarter *t* being associated with an increasing pattern of expense transfer beyond quarter *t*+4.

Taken together, the evidence in Table 4 is consistent only with the increasing form of expense transfer. We find no evidence of zero or positive coefficients after quarter *t*+4 that would suggest a constant or declining form of expense transfer. However, it is conceivable that NSIs contain larger transfers of year +2 (i.e., quarters *t*+5 to *t*+8) expenses relative to year +1 (i.e., quarters *t*+1 to *t*+4) expenses. Such an increasing pattern of expense transfer could potentially explain the significantly negative *RNSI* coefficients in quarters *t*+5 through *t*+8. At the same time, if the increases to earnings truly reflect expense transfer, evidence of necessary reversals should be present by year +3 or +4 (i.e., quarters *t*+9 through *t*+12 and *t*+13 through *t*+16). Our results do not reflect such reversals in quarters *t*+9 through *t*+16, which would imply positive coefficient estimates. Of the 32 *RNSI* coefficient estimates we report in bold in Panel B of Table 4 for the quarters *t*+9 through *t*+16, all but one are negative and 23 of these are significantly less than zero (two-tailed $p < 0.05$).

The evidence in Table 4 is inconsistent with the declining or constant assumptions of the expense-transfer hypothesis. However, these results can be interpreted as providing support for the expense-transfer hypothesis under the increasing transfer assumption. This interpretation requires the seemingly unlikely assumption that the typical or average NSI consists of expense transfers that are monotonically declining from year +4 back through year +1. That is, expenses further in the future are transferred into current NSIs to a greater extent than near-term expenses. Once again, it

[a] A "straddle" earnings change is defined as those instances where $t+k-l \geq t$ and $t+k-l-4 \leq t$. That is, the later earnings value is for a quarter after the NSI quarter and the earlier earnings value is from a quarter prior to the NSI quarter.

[b] A post-special-items change is defined as those instances where $t+k-l-4 > t$. That is, both earnings measures in the seasonally differenced earnings are values that occur after the NSI quarter.

[c] Numbers in bold refer to quarters t+9 through t+16.

Variable Definitions:

$PTI_{i,t+k}$ = pre-tax income (PIQ) for firm i in quarter $t+k$ (where $k = 1,\ldots,$or 16) divided by the market value of equity (MKVALTQ) in quarter t–4; and

$RNSI_{i,t}$ = pre-tax negative special items (SPIQ) for firm i in quarter t divided by the market value of equity (MKVALTQ) in quarter t–4.

appears more plausible that the earnings increases are the result of efficiency improvements after the NSI recognition, such as an effective restructuring, or a combination of efficiency gains and expense transfer. We further explore whether NSIs lead to expense transfer or real improvements in the following sections.

Expense Transfer or Real Improvements?

The evidence from Tables 3 and 4 does not preclude the possibility that NSI-induced expense transfer exists. To more fully explore the extent to which NSIs are associated with expense transfer versus efficiency gains, we estimate the following two regression equations:

$$\Sigma 4QPTI_{i,y} = b_{0y} + b_{1y}RNSI_{i,t} + b_{2y}(PTI_{i,t} - RNSI_{i,t} - PTI_{i,t-4}) + e_{i,t}, \tag{4}$$

and:

$$\Sigma 4QCFO_{i,y} = b_{0y} + b_{1y}RNSI_{i,t} + b_{2y}(PTI_{i,t} - RNSI_{i,t} - PTI_{i,t-4}) + e_{i,t}, \tag{5}$$

where:

$PTI_{i,t+k}$ = pre-tax income (PIQ) for firm i in quarter $t+k$ (where $k = 1,\ldots,16$) divided by the market value of equity (MKVALTQ) in quarter $t-4$;

$CFO_{i,t+k}$ = cash flow from operating activities (OANCFQ) for firm i in quarter $t+k$ (where $k = 1,\ldots,16$) divided by the market value of equity (MKVALTQ) in quarter $t-4$;

$\Sigma 4QPTI_{i,y} = (PTI_{i,t+k} - PTI_{i,t+k-4})$ summed for the four quarters where k equals $1,\ldots,4$ for $y = 1$; $5,\ldots,8$ for $y = 2$; $9,\ldots,12$ for $y = 3$; and $13,\ldots,16$ for $y = 4$; and

$\Sigma 4QCFO_{i,y} = (CFO_{i,t+k} - CFO_{i,t+k-4})$ summed for the four quarters where k equals $1,\ldots,4$ for $y = 1$; $5,\ldots,8$ for $y = 2$; $9,\ldots,12$ for $y = 3$; and $13,\ldots,16$ for $y = 4$.

All other variables are as previously defined. $\Sigma 4QPTI_{i,y}$ and $\Sigma 4QCFO_{i,y}$ are year-by-year, four-quarter summations of the seasonal differences in earnings and operating cash flows, respectively. We estimate Equations (4) and (5) for the four years subsequent to quarter t (i.e., quarters $t+1$ through $t+16$). Equation (4) allows us to measure the annually cumulated future earnings increases that result from the quarter t NSI. Equation (5) allows us to measure the extent to which the NSI in quarter t results in annually cumulated future increases in operating cash flows.

This portion of our analysis has similarities to, and distinctions from, prior work by Doyle et al. (2003) on the relation between future cash flows and items excluded from pro forma income numbers. They find that such excluded items, many of which are special items, have directionally consistent implications for future cash flows. That is, excluded expenses predict lower future cash flows, while excluded income items predict higher future cash flows. However, when Doyle et al. (2003) partition excluded items into special items and other excluded items, they report mixed evidence regarding the relation between special items and future cash flows. In particular, they report an insignificant relation between special items and operating cash flows, but a significantly positive relation with free cash flow (Doyle et al. 2003, 160–161, Tables 3 and 4).

Several important distinctions between Doyle et al. (2003) and this study should be noted. First, Doyle et al. (2003) do not partition special items into negative and positive amounts, whereas our entire focus is on the particular impact of NSIs documented in BJS. Second, their specification includes an accrual explanatory variable. This means that for accrued special items, the estimated coefficient reflects the marginal association of the item with future cash flows above and beyond its accrual effect, which has an opposite directional effect in their analysis. Third, their analysis is done using after-tax special item measures based on the top statutory tax rate. The earlier results in this study as well as the results in Beaver et al. (2006) suggest that such tax adjustments are problematic for NSIs.

Table 5 reports the coefficients from the estimation of Equations (4) and (5) as well as the annual change percentage implied by the coefficients and the cumulative change percentage from summed annual percentages. Estimation of Equation (5) requires additional data not incorporated in earlier tests. We follow the same screening procedures as discussed previously. Our data requirements and sample selection criteria result in a test sample of 36,609 (33,901) NSI observations with complete data to estimate Equation (4) (Equation (5)) for the first four years subsequent to quarter *t*.

The Equation (4) results are consistent with our prior tabulated evidence. In particular, we find that NSIs are associated with significant increases in earnings in each of the four years subsequent to the event quarter. The year +1 coefficient suggests that income increases in the first four quarters subsequent to the NSI by 8.6 percent of the quarter *t* NSI, while over the next four quarters (year +2) the estimated increase in income approximately doubles to generate a cumulative increase of 26.4 percent at the end year +2.[23] In years +3 and +4 we find income increases by another 40.6 and 56.2 percent of the NSI, respectively. Taken together, our evidence suggests that over the first 16 quarters subsequent to the charge, NSI-induced earnings increases equal more than 130 percent of the charge. As a practical matter, special-items-induced expense transfer is bounded by the amount of the NSI and must necessarily be less than 100 percent of the charge if the NSI contains *any* contemporaneous costs (classification shifting or true special item costs). Thus, our evidence suggests that realized efficiency gains over the subsequent 16 quarters equal *at least* 31.8 percent of the NSI.

We next examine the results from the estimation of Equation (5), which relates the NSI to future seasonally adjusted changes in operating cash flows. Because operating cash flows are less susceptible to manipulation by management, any NSI-induced increases in operating cash flows are more likely a result of efficiency gains than expense transfer. Our evidence suggests that NSIs are associated with substantial future increases in operating cash flows. Specifically, we find that over the first four years subsequent to the charge, NSI-induced increases in operating cash flows equal more than 40 percent of the charge. Our evidence suggests that a substantial portion of the future earnings increase related to the NSI is very likely the result of efficiency improvements rather than expense transfer.

Finally, the evidence from both Equations (4) and (5) suggests that the future earnings and cash flow effects of a current NSI are increasing over time. In particular, our evidence suggests that earnings increase by 8.6, 26.4, 40.6, and 56.2 percent of the quarter *t* NSI in years +1, +2, +3, and +4, respectively. Similarly, our evidence suggests that cash flows increase (decrease) by (0.6), 1.8, 12.8, and 26.2 percent of the quarter *t* NSI in years +1, +2, +3, and +4, respectively. This evidence is broadly consistent with NSIs being associated with real improvements since cash flow increases and expense transferred from four years in the future seems very unlikely to explain the earnings increases of the magnitude noted.

---

[23] Since the dependent variables in Equations (4) and (5) are annually cumulated measures of seasonally differenced earnings or cash flows (e.g., $\Sigma 4QPTI_{i,y}$ for year +2 is the summed $(PTI_{i,t+k} - PTI_{i,t+k-4})$ for quarters t+6 to t+9), to determine the income and cash flow effect of the NSI in years beyond $y = 1$, the *RNSI* coefficients must be evaluated with respect to the coefficients for the prior year. For example, in year 1 the coefficient on *RNSI* in Equation (4) is −1.086 suggesting that pre-tax income (*PTI*) increases (NSIs enter as negative amounts) in year +1 relative to the year prior to quarter *t* by 8.6 percent of the NSI. In year +2 the coefficient on *RNSI* is −0.178 suggesting that special items-induced PTI increased in year +2 relative to year +1 by 17.8 percent of the NSI. Since earnings in year +1 are higher by 8.6 percent of the NSI, the total effect is that *PTI* increased in year +2 by 26.4 percent of the quarter *t* NSI relative to pre-special items earnings. The 26.4 percent is the amount we report in Panel A of Table 5 as the annual increase in year +2 *PTI*. This same procedure holds for calculating the cash flow increase induced by the NSI since this is also a seasonally adjusted measure.

TABLE 5

Relationship between Pre-Tax Negative Special Items and Seasonally Adjusted Pre-Tax Future Earnings and Operating Cash Flows for Years +1 through +4 Estimated b_{1y} from Equations (4) and (5):

*, ** Significantly different from zero at the 0.05 and 0.01 levels, respectively, in a two-tailed test.

+, ++ Significantly different from −1 at the 0.05 and 0.01 levels, respectively, in a two-tailed test (applies only for estimates of b_1 at $y = 1$).

[a] This is the percentage of the quarter t negative special item reflected in earnings and cash flows for years 1 through 4. For example, in Panel A for $\Sigma 4QPTI$ for $y = 2$ the 26.4 suggests the pre-tax income for quarters $t+5$ through $t+8$ (i.e., $y = 2$) increased by 26.4 percent of the *RNSI* relative to year 0.

[b] This represents the cumulative percentage impact of the quarter t negative special item on earnings and operating cash flows for quarters years +1 through +4.

Variable Definitions:

$PTI_{i,t+k}$ = pre-tax income (PIQ) for firm i in quarter $t+k$ (where $k = 1,\ldots,$or 16) divided by the market value of equity (MKVALTQ) in quarter $t-4$;

$RNSI_{i,t}$ = pre-tax negative special items (SPIQ) for firm i in quarter t divided by the market value of equity (MKVALTQ) in quarter $t-4$;

$CFO_{i,t+k}$ = cash flow from operating activities (OANCFQ) for firm i in quarter $t+k$ (where $k = 1,\ldots,$or 16) divided by the market value of equity (MKVALTQ) in quarter $t-4$;

$\Sigma 4QPTI_{i,y} = (PTI_{i,t+k} - PTI_{i,t+k-4})$ summed for the four quarters where k equals $1,\ldots,4$ for $y = 1$; $5,\ldots, 8$ for $y = 2$; $9,\ldots,12$ for $y = 3$; and $13,\ldots, 16$ for $y = 4$; and

$\Sigma 4QCFO_{i,y} = (CFO_{i,t+k} - CFO_{i,t+k-4})$ summed for the four quarters where k equals $1,\ldots,4$ for $y = 1$; $5,\ldots,8$ for $y = 2$; $9,\ldots, 12$ for $y = 3$; and $13,\ldots,16$ for $y = 4$.

Taken together, the results from estimating Equations (4) and (5) suggest that efficiency gains account for at least 30 percent of the earnings increases we document in Table 5. This estimate appears to be the lower bound on efficiency improvements because all increases in the accrual component of earnings are certainly not the result of expense transfer. Overall, our empirical evidence is not supportive of the expense-transfer hypothesis as the sole explanation for the results we observe. The pattern of *NSI* coefficients we observe is broadly consistent with NSIs representing a substantive repositioning or strategy shift by the entity where the primary benefit is received over a number of periods in the future. While we cannot fully disentangle the effects of these hypotheses for all special items, the differing implications of sub-types of special items may shed light on these inferences.

Restructuring Charges, Asset Write-Downs, and Goodwill Impairment

Our Table 5 results suggest that NSIs lead to substantial increases in earnings and operating cash flows that we attribute to both real improvements and expense transfer. In this section, we focus on the special item sub-types that we expect will have differing implications for future earnings and cash flows. In particular, we separately examine the future earnings and cash flow implications of restructuring charges, asset write-downs, and goodwill impairment charges. In so doing, we focus on NSI sub-types that are most likely to be associated with efficiency improvements, expense transfer, or those that should be purely transitory, respectively.

To the extent that NSIs are associated with future efficiency gains, we expect that restructuring charges will most likely lead to these gains (Brickley and Van Drunen 1990; Atiase et al. 2004; Clement et al. 2007). On the other hand, we expect asset write-downs to be most closely associated with the type of charge that represents an acceleration of future expense or expense transfer since future depreciation expense is brought forward into the quarter of recognition. Goodwill impairment charges do not promote efficiency gains nor are they an acceleration of future expenses since goodwill is not amortized in our sample period.

To more fully explore the extent to which these NSI sub-types are associated with future earnings and operating cash flows, we estimate the following two regression equations:

$$\begin{aligned}\Sigma 4QPTI_{i,y} = {} & b_{0y} + b_{1y}RC_{i,t} + b_{2y}WD_{i,t} + b_{3y}GW_{i,t} + b_{4y}OTHER\_NSI_{i,t} \\ & + b_{5y}(PTI_{i,t} - RNSI_{i,t} - PTI_{t-4}) + e_{i,t},\end{aligned} \tag{6}$$

and:

$$\begin{aligned}\Sigma 4QCFO_{i,y} = {} & b_{0y} + b_{1y}RC_{i,t} + b_{2y}WD_{i,t} + b_{3y}GW_{i,t} + b_{4y}OTHER\_NSI_{i,t} \\ & + b_{5y}(PTI_{i,t} - RNSI_{i,t} - PTI_{t-4}) + e_{i,t},\end{aligned} \tag{7}$$

where:

$RC_{i,t}$ = pre-tax restructuring charges (RCPQ) for firm i in quarter t divided by the market value of equity (MKVALTQ) in quarter t–4;
$WD_{i,t}$ = pre-tax asset write-downs (WDPQ) for firm i in quarter t divided by the market value of equity (MKVALTQ) in quarter t–4;
$GW_{i,t}$ = pre-tax goodwill write-offs (GDWLIPQ) for firm i in quarter t divided by the market value of equity (MKVALTQ) in quarter t–4; and
$OTHER\_NSI_{i,t} = RNSI_{i,t} - RC_{i,t} - WD_{i,t} - GW_{i,t}$.

All other variables are as previously defined. We estimate Equations (6) and (7) for the four years subsequent to quarter t, quarters t+1 through t+16 (years +1 through +4).

Table 6 reports the coefficients from the estimation of Equations (6) and (7) as well as the cumulative change percentage implication of each special item sub-type for future earnings and cash flows. Consistent with our expectation, the Equation (6) results suggest that the future earnings implications of restructuring charges (*RC*s) are greater than those of asset write-downs (*WD*s) and goodwill impairment charges (*GW*s). Specifically, our evidence suggests that earnings increase over the subsequent four years by 573 percent of *RC*s, 152 percent of *WD*s, and 38 percent of *GW*s. The future cash flow results from the estimation of Equation (7) are consistent with the Equation (6) results. In particular, we find that operating cash flows increase over the subsequent four years by 156 percent of *RC*s, 66 percent of *WD*s, and *GW*s actually lead to a decrease in future cash flows

TABLE 6

Relation between Pre-Tax Restructuring Charges, Asset Write-downs, Goodwill Write-Offs, and Other Special Items and Seasonally Adjusted Future Earnings and Cash Flows Estimates of b_{1y}, b_{2y}, b_{3y}, and b_{4y} for years $y = 1$ through $y = 4$ from Equations (6) and (7):

*, ** Significantly different from zero at the 0.05 and 0.01 levels, respectively, in a two-tailed test.

++ Significantly different from −1 at the 0.01 level in a two-tailed test (applies only for estimates of b_1 at $y = 1$).

[a] This represents the cumulative percentage impact of the quarter *t* negative special item on earnings and operating cash flows for quarters years +1 through +4.

Variable Definitions:

$PTI_{i,t+k}$ = pre-tax income (PIQ) for firm *i* in quarter *t*+*k* (where $k = 1,\ldots,$or 16) divided by the market value of equity (MKVALTQ) in quarter *t*–4;

$RNSI_{i,t}$ = pre-tax negative special items (SPIQ) for firm *i* in quarter *t* divided by the market value of equity (MKVALTQ) in quarter *t*–4;

$CFO_{i,t+k}$ = cash flow from operating activities (OANCFQ) for firm *i* in quarter *t*+*k* (where $k = 1,\ldots,$or 16) divided by the market value of equity (MKVALTQ) in quarter *t*–4;

$\Sigma 4QPTI_{i,y} = (PTI_{i,t+k} - PTI_{i,t+k-4})$ summed for the four quarters where *k* equals 1,. . .,4 for $y = 1$; 5,. . .,8 for $y = 2$; 9,. . .,12 for $y = 3$; and 13,. . .,16 for $y = 4$.

$\Sigma 4QCFO_{i,y} = (CFO_{i,t+k} - CFO_{i,t+k-4})$ summed for the four quarters where *k* equals 1,. . .,4 for $y = 1$; 5,. . .,8 for $y = 2$; 9,. . .,12 for $y = 3$; and 13,. . .,16 for $y = 4$.

(continued on next page)

TABLE 6 (continued)

$RC_{i,t}$ = pre-tax restructuring charges (RCPQ) for firm i in quarter t divided by the market value of equity (MKVALTQ) in quarter t–4;
$WD_{i,t}$ = pre-tax asset write-downs (WDPQ) for firm i in quarter t divided by the market value of equity (MKVALTQ) in quarter t–4;
$GW_{i,t}$ = pre-tax goodwill write-offs (GDWLIPQ) for firm i in quarter t divided by the market value of equity (MKVALTQ) in quarter t–4; and
$OTHER\_NSI_{i,t} = RNSI_{i,t} - RC_{i,t} - WD_{i,t} - GW_{i,t}$.

equal to 12 percent of the charge. Thus, we find increases in earnings and cash flows where we expect to find them with *RC*s and no impact where we expect there to be none with *GW*s.

Our results with respect to *WD*s are not entirely consistent with our expectation. We expected to see future earnings increases associated with the *WD* that fit the expense transfer scenario. That is, expected future earnings increases should not exceed 100 percent of the *WD* and evidence of declining earnings should exist in post-NSI change years (i.e., years +2 and beyond). However, the estimated cumulative increases in future earnings exceed 100 percent of the *WD* and the significantly positive coefficient on *WD* in year +4 provides only limited evidence of any sort of earnings decline. Overall, our Table 6 evidence with respect to *WD*s is inconsistent with these charges solely representing expense transfer. On the contrary, our evidence is more consistent with *WD*s having strategic implications. That is, strategy shifts lead to existing assets being used differently, triggering both the current *WD* and future improvements to earnings and operating cash flows. Consistent with this notion, we find that when a firm recognizes a *WD*, the firm also recognizes an *RC* 30 percent of the time.

To better address the impact of individual types of charges, we estimate Equations (6) and (7) for observations in which each of the individual special item sub-types are reported in isolation.[24] For example, for this set of tests we only include restructuring observations when all other NSI sub-types are zero. The results of these additional untabulated tests are consistent with our tabulated results in Table 6. For restructuring charges, we find *RC*-induced increases in earnings and cash flows over the four years subsequent to recognition of approximately 435 and 117 percent of the *RC*, respectively. Similarly, for *WD*s, we find *WD*-induced increases in earnings and cash flows over the four years subsequent to recognition of approximately 127 and 73 percent of the *WD*, respectively. With respect to *GW*s, we find earnings and cash flow increases of 10 and 17 percent, respectively. Thus, even when we require that these special item sub-types be reported in isolation, we still find increases in earnings and cash flows where we expect to find them with *RC*s and no impact where we expect there to be none with *GW*s.

Sensitivity Analyses

We believe our evidence supports the conclusion that, on average, real improvements are at least as important as expense transfer in determining the NSI-induced increases in earnings and cash flows for three reasons. First, we estimate NSI-induced earnings increases that exceed 130 percent of the NSI and 40 percent of this increase comes from increases to operating cash flows. Second, most of this increase is realized in years +3 and +4, which seems more likely to be the result of real performance improvements than a long-term expense transfer effect. Third, the increasing pattern of NSI-induced earnings we observe over the four years subsequent to recognition is broadly consistent with real improvements but not with expense transfer as the primary explanation.

---

[24] We thank an anonymous referee for this suggestion.

That said, our results so far do not preclude a significant expense transfer effect in the data. To address this limitation, we offer additional tests, based on Riedl (2004), designed to shed some light on which of the two effects is more prevalent. Riedl (2004) concludes that asset impairments exhibit weaker association with the economic predictors of asset impairments in the post- versus pre-SFAS 121 period.[25] In addition, Riedl (2004) reports a higher association between asset impairments and "big bath" behavior after the enactment of SFAS 121. He concludes that big bath behavior reflects opportunistic reporting by managers rather than providing private information about the underlying performance of the firm, a notion consistent with big bath behavior being associated with expense transfer as opposed to real improvements.

If Riedl's (2004) findings extend to our setting, then we should find evidence more consistent with the declining expense transfer assumption for (1) post- versus pre-SFAS 121 and (2) big bath versus non-big bath behavior. For the post- versus pre-SFAS 121 tests (post-1996 versus pre-1995), we use all data to estimate Equation (4) for the years 1981 through 2009. The untabulated results of this test suggest no post- versus pre-SFAS 121 difference in the total NSI-induced earnings over the subsequent four years (127.6 and 119.6 percent of the NSI, respectively). In addition, the pattern of increases between the two subsamples is nearly identical.

Riedl (2004) identifies big bath observations as those firms with a negative change in pre-write-off earnings that is less than the median for all firms with a negative change in pre-write-off earnings.[26] Using the same sample from Table 5, untabulated results indicate that the total NSI-induced increases over the subsequent four years are greater for the non-big bath sample than the big bath sample (117 to 71 percent). In addition, we find that most of the increases for the big bath sample are in the first two years (increases of 8, 31, 24, and 8 percent for years 1, 2, 3, and 4, respectively), while the increases for the non-big bath sample are more concentrated in the last two years (increases of 5, 21, 34, and 58 percent for the same years, respectively). Thus, for the big bath sample, our results suggest evidence of reversal in years +3 and +4 (i.e., declining increases), while for the non-big bath sample our evidence suggests further increases in those same years.[27] Taken together, our evidence is consistent with expense transfer for those firms identified as most likely to be engaged in big bath behavior. However, the overwhelming majority of the sample firms do not engage in big bath behavior and the evidence with respect to these firms is more consistent with real improvements.

Prior Performance

Prior research provides compelling evidence that NSI firms underperform in the periods leading up to the recognition of the NSI (e.g., Dechow and Ge 2006; Fairfield et al. 2009). Since our analysis involves future changes in performance, our evidence of improved earnings and cash flows may be related to underperformance prior to recognition of the NSI. That is, underperforming firms have more room for improvement than highly performing firms. Accordingly, we investigate this by incorporating a matched-firm design to specifically control for pre-special item performance.[28] In particular, we estimate the following three regression equations:

---

[25] Statement of Financial Accounting Standards (SFAS) No. 121, *Accounting for the Impairment of Long-Lived Assets*, was enacted in 1995.

[26] Riedl (2004, 833) addresses the measure of big bath (*BATH*) in his manuscript. Where he uses annual data and yearly changes, we substitute seasonal changes in pre-NSI earnings.

[27] We also perform this test on a sample of restructuring observations because these events are equally susceptible to both expense transfer and real improvement. Untabulated tests show that the total RC-induced earnings increases are greater for the non-big bath sample than the big bath sample (433 to 62 percent). In addition, the big bath sample actually shows a decrease in year +4 (i.e., evidence of reversal), while the non-big bath sample continues to show increases over all four years subsequent to recognition.

[28] Firms reporting an NSI in quarter t are matched by four-digit SIC to all non-NSI counterpart firms in the same industry, year, and quarter leaving zero or positive special item firms as a potential matched control firm. The NSI firm is then matched to the non-NSI firm with the smallest difference in four-quarter, pre-SI earnings growth over the four quarters prior to quarter t, defined as $[(E_{i,t} - SI_{i,t})/(E_{i,t-4} - SI_{i,t-4})] - 1$.

$$M\_\Delta PTI_{i,t+k} = b_{0k} + b_{1k}RNSI_{i,t} + b_{2k}(PTI_{i,t} - RNSI_{i,t} - PTI_{i,t-4}) + e_{i,t}, \tag{8}$$

$$M\_\Sigma 4QPTI_{i,y} = b_{0y} + b_{1y}RNSI_{i,t} + b_{2y}(PTI_{i,t} - RNSI_{i,t} - PTI_{i,t-4}) + e_{i,t}, \tag{9}$$

$$M\_\Sigma 4QCFO_{i,y} = b_{0y} + b_{1y}RNSI_{i,t} + b_{2y}(PTI_{i,t} - RNSI_{i,t} - PTI_{i,t-4}) + e_{i,t}, \tag{10}$$

where:

$M\_PTI_{i,t+k}$ = pre-tax income (PIQ) for non-NSI control firm *i* in quarter $t+k$ (where $k = 1,\ldots,4$) divided by the market value of equity (MKVALTQ) in quarter $t-4$;
$M\_CFO_{i,t+k}$ = cash flow from operating activities (OANCFQ) for non-NSI control firm *i* in quarter $t+k$ (where $k = 1,\ldots,16$) divided by the market value of equity (MKVALTQ) in quarter $t-4$;
$M\_\Delta PTI_{i,t+k} = [(PTI_{i,t+k} - PTI_{i,t+k-4}) - (M\_PTI_{i,t+k} - M\_PTI_{i,t+k-4})]$;
$M\_\Delta CFO_{i,t+k} = [(CFO_{i,t+k} - CFO_{i,t+k-4}) - (M\_CFO_{i,t+k} - M\_CFO_{i,t+k-4})]$;
$M\_\Sigma 4QPTI_{i,y} = M\_\Delta PTI_{i,t+k}$ summed for the four quarters where *k* equals $1,\ldots,4$ for $y = 1$; $5,\ldots,8$ for $y = 2$; $9,\ldots,12$ for $y = 3$; and $13,\ldots,16$ for $y = 4$; and
$M\_\Sigma 4QCFO_{i,y} = M\_\Delta CFO_{i,t+k}$ summed for the four quarters where *k* equals $1,\ldots,4$ for $y = 1$; $5,\ldots,8$ for $y = 2$; $9,\ldots,12$ for $y = 3$; and $13,\ldots,16$ for $y = 4$.

All other variables are as previously defined. This design subtracts the values of the independent variables for the control firm from the NSI firm to assess the effect, if any, of performance prior to the recognition of an NSI. We estimate Equation (8) for the four quarters subsequent to quarter *t* and Equations (9) and (10) for the four years subsequent to quarter *t*. Equation (8) allows us to assess the impact of controlling for prior performance on our Equation (2) results reported in Table 3. Equations (9) and (10) allow us to assess the impact of controlling for prior performance on our Equation (4) and (5) results reported in Table 5. We report the results of Equations (8), (9), and (10) in Table 7, Panels A, B, and C, respectively. In addition and for direct comparison, we re-estimate the corresponding Equations (2), (4), and (5) on the reduced subsample used for these tests.

In Panel A of Table 7, the matched control firm adjusted future earnings ($M\_\Delta PTI_{i,t+k}$) for quarters $t+1$ through $t+4$ suggests special item-induced earnings increases over the subsequent four quarters of approximately 6.7 percent of the NSI. This is almost exactly the same amount estimated in Equation (2), also reported in Panel A, where we find the increase is approximately 5.9 percent. We find similar evidence with respect to earnings and cash flow changes over the subsequent four years. In Panel B, our evidence suggests the matched control firm adjusted future earnings increase 106.9 percent of the NSI. And in Panel C, we find that the matched control firm adjusted future cash flows increase 65.9 percent of the NSI. Taken together, the evidence in Table 7 suggests that reversal of prior performance does not explain our results.[29]

Special Item Reporting Frequency

Cready et al. (2010) report that the market prices NSIs differently depending on prior reporting frequency. In particular, they report that as the prior reporting frequency increases, the pricing multiple on NSIs increases, consistent with the market treating recurring NSIs more like operating expenses than transitory items. In addition, Cready et al. (2010) and Johnson et al. (2011) report evidence that past reporting frequency predicts future reporting of NSIs. That is, the future

---

[29] We also match NSI firms to non-NSI firms using cumulative four quarter earnings (scaled) for quarters $t-4$ to $t-1$ as a proxy for prior performance. Our results are robust to this alternative method.

Variable Definitions:

$PTI_{i,t+k}$ = pre-tax income (*PIQ*) for firm *i* in quarter $t+k$ (where $k = 1,\ldots,$or 4) divided by the market value of equity (*MKVALTQ*) in quarter $t-4$;

$RNSI_{i,t}$ = pre-tax negative pre-tax special items (*SPIQ*) for firm *i* in quarter *t* divided by the market value of equity (*MKVALTQ*) in quarter $t-4$;

$CFO_{i,t+k}$ = cash flow from operating activities (*OANCFQ*) for firm *i* in quarter $t+k$ (where $k = 1,\ldots,$or 16) divided by the market value of equity (*MKVALTQ*) in quarter $t-4$;

$\Sigma 4QPTI_{i,y} = (PTI_{i,t+k} - PTI_{i,t+k-4})$ summed for the four quarters where *k* equals $1,\ldots,4$ for $y = 1$; $5,\ldots,8$ for $y = 2$; $9,\ldots,12$ for $y = 3$; and $13,\ldots,16$ for $y = 4$;

$\Sigma 4QCFO_{i,y} = (CFO_{i,t+k} - CFO_{i,t+k-4})$ summed for the four quarters where *k* equals $1,\ldots,4$ for $y = 1$; $5,\ldots,8$ for $y = 2$; $9,\ldots,12$ for $y = 3$; and $13,\ldots,16$ for $y = 4$;

$M\_PTI_{i,t+k}$ = pre-tax income (*PIQ*) for non-*NSI* control firm *i* in quarter $t+k$ (where $k = 1,\ldots,$or 16) divided by the market value of equity (*MKVALTQ*) in quarter $t-4$;

$M\_CFO_{i,t+k}$ = cash flow from operating activities (*OANCFQ*) for non-NSI control firm *i* in quarter $t+k$ (where $k = 1,\ldots,16$) divided by the market value of equity (*MKVALTQ*) in quarter $t-4$;

$M\_\Delta PTI_{i,t+k} = [(PTI_{i,t+k} - PTI_{i,t+k-4}) - (M\_PTI_{i,t+k} - M\_PTI_{i,t+k-4})]$;

$M\_\Sigma 4QPTI_{i,y} = [(PTI_{i,t+k} - PTI_{i,t+k-4}) - (M\_PTI_{i,t+k} - M\_PTI_{i,t+k-4})]$ summed for the four quarters where *k* equals $1,\ldots,4$ for $y = 1$; $5,\ldots,8$ for $y = 2$; $9,\ldots,12$ for $y = 3$; and $13,\ldots,16$ for $y = 4$; and

$M\_\Sigma 4QCFO_{i,y} = [(CFO_{i,t+k} - CFO_{i,t+k-4}) - (M\_CFO_{i,t+k} - M\_CFO_{i,t+k-4})]$ summed for the four quarters where *k* equals $1,\ldots,4$ for $y = 1$; $5,\ldots,8$ for $y = 2$; $9,\ldots,12$ for $y = 3$; and $13,\ldots,16$ for $y = 4$.

persistence of the NSI is linked to past reporting. Thus, the evidence we report with respect to future earnings increases may be influenced by prior reporting frequency.

To address this issue, we re-estimate Equations (2), (4), and (5) conditioned on NSI reporting frequency over the prior four years. The cumulative change percentage we find over the subsequent four quarters is (0.6), 11.5, 20.3, 13.2, and 12.3 percent of the NSI for observations with zero, one, two, three, and four prior NSIs, respectively. With respect to the re-estimation of Equation (4), we find subsequent NSI-induced cumulative earnings increases over the subsequent four years of 135 (128) percent for NSI observations preceded by one (four) prior NSI(s). Similarly with respect to the re-estimation of Equation (5), we find cumulative NSI-induced increases to cash flows over the subsequent four years of 70 (61) percent for NSI observations preceded by one (four) prior NSI(s).

Thus, the untabulated evidence from these tests is generally consistent with the conclusion that reporting frequency is largely unrelated to future earnings changes over the subsequent four quarters and four years, respectively.

Survivorship Bias

Our conclusion that NSIs lead to performance improvements is potentially explained by "survivors" that naturally perform better than firms that fail to survive subsequent to recognition of an NSI. To more fully examine this notion, we create two samples ("survivors" and "non-survivors") to ascertain the effect of survivorship bias on our results. We use these two samples to re-estimate Equations (4) and (5). A "survivor" is defined as an observation that has complete data to estimate Equation (4) or (5) for each of the four years subsequent to NSI recognition. On the other hand, a "non-survivor" is defined as an observation that has complete data to estimate Equation (4) or (5) for year +1 but does not have complete data for the years +2, +3 and +4. The results from the estimation of Equations (4) and (5) for the survivor and non-survivor samples are reported in Table 8 Panels A and B, respectively. We limit this examination to the three years subsequent to the NSI recognition because our data restricts us in creating a non-survivor sample to these particular years.

The Equation (4) results for the "survivor" sample are consistent with our prior tabulated evidence in Table 5. In particular, in Table 8, Panel A we find that NSIs are associated with significant increases in earnings in each of the three years subsequent to the event quarter. Taken together, our evidence suggests that over the first 12 quarters subsequent to the charge, NSI-induced earnings increases equal more than 123 percent of the charge. We next examine the results from the estimation of Equation (5) that relates the NSI to future seasonally adjusted changes in operating cash flows. Our evidence suggests that NSIs are associated with substantial future increases in operating cash flows. Specifically, we find that over the first 12 quarters subsequent to the charge, NSI-induced increases in operating cash flows equal more than 19 percent of the charge. Thus, our evidence suggests substantial NSI-induced increases in earnings and cash flows for the "survivor" sample that we would expect to perform the best subsequent to the NSI recognition.

However, our evidence in Table 8, Panel B suggests that survivorship bias is not driving our primary conclusions. Consistent with this notion, we find NSI-induced earnings increases for our non-survivor sample over the subsequent three years of 93.2 percent of the NSI. While not as great as the increases found for our sample of survivors in Panel A (123.1 percent), it is greater than the increases documented for the full sample in Table 5 (75.6 percent). Our evidence with respect to operating cash flows (estimation of Equation (5)) is similar to the earnings results. We find NSI-induced operating cash flow increases over the subsequent three years of 38.7, which is greater than the survivor sample in Panel A and the full sample results we report in Table 5 of 19.2 and 14.0 percent, respectively. While we cannot fully rule out a survivor effect, our evidence does not support the conclusion that survivorship bias drives our overall results.

Subsequent Special Item Reporting

Finally, we test the impact of subsequent NSI reporting on our results. If a firm engages in a pattern of consistently reporting NSIs, expense transfer may appear to be real improvements. Fairfield et al. (2009) discuss this notion in their study and suggest this as a potential explanation for their result that "some firms maintain high core profitability by becoming serial chargers." To address this possibility as a potential explanation for our results, we re-estimate Equation (4) conditioned on the number of years a firm recognizes an NSI over the subsequent four years. Our evidence suggests no relation between NSI-induced earnings increases and subsequent reporting frequency. In particular, untabulated results reveal NSI-induced earnings increases of 213, 175,

*, ** Significantly different from zero at the 0.05 and 0.01 levels, respectively, in a two-tailed test.

+, ++ Significantly different from −1 at the 0.05 and 0.01 levels, respectively, in a two-tailed test (applies only for estimates of b_1 at $y = 1$).

[a] This is the percentage of the quarter *t* negative special item reflected in earnings and cash flows for years 1 through 4. For example, for *Σ4QPTI* for $y = 2$ the 31.5 suggests the pre-tax income for quarters *t*+5 through *t*+8 (i.e., $y = 2$) increased by 35.7 percent of the *RNSI* relative to year 0.

[b] This represents the cumulative percentage impact of the quarter *t* negative special item on earnings and operating cash flows for years +1 through +4.

(continued on next page)

TABLE 8 (continued)

[c] The "Survivor Sample" requires that each observation have complete data to estimate Equations (4) or (5) for all four years subsequent to the quarter in which the *RNSI* is reported. The "Non-Survivor Sample" requires that the observation have complete data to estimate Equation (4) or (5) in a particular year, but not in any of the subsequent years. For example, the 8,376 observations for the estimation of Equation (4) in $y = 1$ have complete data for the year after the *RNSI* is reported (i.e., year +1), but not for the years subsequent to $y = 1$ (i.e., years +2, +3 and +4).

Variable Definitions:
$PTI_{i,t+k}$ = pre-tax income (*PIQ*) for firm *i* in quarter *t+k* (where $k = 1,\ldots,$or 16) divided by the market value of equity (*MKVALTQ*) in quarter *t*–4;
$RNSI_{i,t}$ = pre-tax negative special items (*SPIQ*) for firm *i* in quarter *t* divided by the market value of equity (*MKVALTQ*) in quarter *t*–4;
$CFO_{i,t+k}$ = cash flow from operating activities (*OANCFQ*) for firm *i* in quarter *t+k* (where $k = 1,\ldots,$or 16) divided by the market value of equity (*MKVALTQ*) in quarter *t*–4;
$\Sigma 4QPTI_{i,y} = (PTI_{i,t+k} - PTI_{i,t+k-4})$ summed for the four quarters where *k* equals 1,. . .,4 for $y = 1$; 5,. . .,8 for $y = 2$; 9,. . .,12 for $y = 3$; and 13,. . .,16 for $y = 4$; and
$\Sigma 4QCFO_{i,y} = (CFO_{i,t+k} - CFO_{i,t+k-4})$ summed for the four quarters where *k* equals 1,. . .,4 for $y = 1$; 5,. . .,8 for $y = 2$; 9,. . .,12 for $y = 3$; and 13,. . .,16 for $y = 4$.

202, 64, and 219 percent of the NSI for firms with zero, one, two, three, and four subsequent annual NSIs, respectively.

V. CONCLUSION

In a path-breaking study of the time-series earnings implications of special items, Burgstahler et al. (2002; hereafter, BJS) provide evidence that suggests that the market fails to fully impound the predictable future earnings implications of special items. They also report that NSIs signal sizable increases in earnings over the subsequent four quarters. In fact, their evidence suggests that firms realize over 56 percent of the NSI in earnings over the subsequent four quarters. They conjecture that inter-period transfer of expense is the likely explanation for this observed relation between NSIs and future earnings. That is, firms accelerate the recognition of future period expenses in the form of a current NSI and thereby artificially boost future income.

The BJS conclusion that NSIs represent the current recognition of future period expenses is of particular interest for several reasons. First, these items are relatively transparent because unusual or infrequent items are separately identified on the income statement, disclosed in the footnotes, or both.[30] Second, the timing, classification, and magnitude of NSI recognition in certain circumstances represents a voluntary choice by management. Hence, the use of NSIs to opportunistically shift expenses from one period to another or from a normal operating category to an unusual or infrequent category supports the notion that voluntary disclosure environments are associated with adverse information quality. Third, identification and recognition of expenses in appropriate time periods is a bedrock principle of financial accounting (FASB Statement of Financial Accounting Concepts No. 5). If special items serve, as BJS suggest, primarily as a device for circumventing the recognition of expenses in appropriate reporting periods, then rules governing the recognition of special items may need improvement. Finally, the market's positive valuation of subsequent earnings increases documented in BJS raises the possibility that the market is fooled not only by the initial recognition of NSIs, which are over-discounted, but also by the subsequent predictable increases to earnings, which are over-valued.[31] That is, the inter-period transfer hypothesis suggests that future earnings induced by the recognition of NSIs may result in an unusually potent market misvaluation effect.[32]

---

[30] NSI charges are often described on the income statement as "special," "unusual," "nonrecurring," "restructuring," or other similar descriptive labels.

Our analysis tests the BJS expense transfer conjecture with respect to its implications for earnings behavior in quarters beyond those immediately following the special items quarter. Under the expense-transfer hypothesis, the earnings increases observed in the first four quarters following NSI recognition must reverse in subsequent quarters. That is, if the observed earnings increases are the result of accelerating future expenses via an NSI, then these earnings increases cannot continue in perpetuity since the cumulative transfer effect is bounded by the amount of the initial charge. We find no evidence of such reversals over the four-year time period following the special item event quarter. Indeed, our evidence suggests that second, third, and fourth year income continues to build on the increases realized in the first year after the special item.

Our evidence can, in part, be explained as reflecting special items consisting of larger amounts of distant-period expenses relative to nearer expenses. However, a more straightforward explanation is that the increasing earnings pattern reflects real improvement in post-NSI firm performance that is either signaled by, or a consequence of, the NSI event. Consistent with this perspective, we find that NSIs are associated with substantial future increases in cash flows from operations. In particular, we find that over 40 percent of the NSI-induced earnings increases we document are realized through increases in operating cash flow. Since operating cash flows are less susceptible to temporal manipulation, our evidence suggests that the earnings increases we document are more likely to be the result of real improvements.

We interpret our evidence as demonstrating that NSIs lead to nontransitory future performance improvements that result from underlying shifts in firm strategies or operations that are costly in the short-run but improve profits in the long-run. Moreover, these long-run effects are an important factor in explaining the pattern of persistent earnings increases that we and BJS observe in post-special-items quarters, especially those beyond the fourth subsequent quarter. At the same time, it is also likely that some firms are engaging in accelerating the recognition of future ongoing expenses via the special item charge. We interpret our evidence as suggesting that such expense transfer effects do not account for the bulk of the predictable earnings behavior occurring in post-special items periods.

Multinational Taxation and R&D Investments

ABSTRACT: This study examines the effects of taxation on the incentives of multinational firms to develop and use intellectual property. We model optimal investment and production decisions by firms that engage in a patent race by making R&D investments. We investigate how taxes affect the level and efficiency of R&D investments, and how these effects depend on whether the winner of the patent race uses it by either producing in the country in which the patent was developed (the domestic country) or in a foreign country. A higher domestic tax rate decreases investment in R&D if production occurs in the domestic country, but increases investment in R&D if production occurs in the foreign country. The present value of domestic tax revenues is strictly positive if production occurs in the domestic country, but is weakly negative if production occurs in the foreign country.

Keywords: *multinational taxation; R&D investment; transfer pricing; patent races.*

I. INTRODUCTION

We examine the effects of taxation on the incentive of a multinational firm to develop and use intellectual property. Intellectual property is an important and growing source of firm value. Lev (2001) attributes much of the tripling in the price-to-book ratios of the S&P 500 over the past 30 years to the value of intellectual property, which is reflected in a firm's market value but not its book value. Because intellectual property lacks a physical manifestation and does not appear as an asset on a firm's balance sheet, it is difficult to ensure that the income that intellectual property generates is taxed by the country in which the property was created. Therefore, the increasing importance of intellectual property poses a challenge to the current system of taxing multinational income, which evolved in an era in which tangible and financial assets were the

dominant sources of firm value. Lev (2001) and Blair and Wallman (2001) provide an overview of the economic, accounting, and taxation issues associated with intangible assets.

We investigate the effects of taxation of intellectual property of multinational firms using a two-stage model. The first stage is the patent race in which many firms compete for a patent. The winner of the race obtains a valuable intangible asset. The second stage is the production stage in which the winner of the patent race uses its intellectual property. We model the full economic environment in which the quasi-rents that the winning firm receives in the second stage are competed away at the industry level in the first stage. Production in the second stage could occur either domestically or in a foreign country. In case of foreign production, the difficulty in valuing intangible assets creates important transfer pricing issues.

The traditional analysis of the taxation of investments in intellectual property (Gravelle 1994, 209) features a single firm that makes a positive net present value investment. The investment is expensed for tax purposes when it is made, and future cash flows from the investment are taxed as they occur. The government collects zero net tax revenue in present value terms on the normal return to capital, and a fraction equal to the statutory tax rate of the pretax net present value of the project. The tax treatment of investments in intangible assets differs from the taxation of investments in tangible assets in that tangible assets are capitalized instead of expensed. As a result, the normal return to capital from tangible investments is taxed.

This traditional analysis of the taxation of investments in intellectual property is incomplete in two respects. First, the analysis begins with a single firm that makes a positive net present value investment. This approach disregards the firms that made unsuccessful investments. In our study, we focus on all of the firms in an industry that try to develop intellectual property, rather than focusing only on the firm that succeeds. All firms that enter the patent race get to deduct their investments; the winning firm's pretax accounting profit from its use of the patent is subject to tax.

Second, the traditional analysis assumes that all of the economic returns to the investment are taxed by the country in which the investment takes place. In our study, we explicitly model the tangible investment needed to exploit the intellectual property once it is created. This tangible investment can be made either in the country in which the intellectual property is created or in a foreign country. When a patent is developed in one country and used in a different country, taxable income is divided between the two countries. The division of taxable income depends on the transfer price paid by the foreign subsidiary to the domestic firm as compensation for the use of the intellectual property. Governments have coordinated on the arm's-length standard for determining transfer prices, in which the results of the transaction are consistent with the results that would have occurred had the transaction taken place between two unrelated parties (Treas. Reg. §1.482-1(b)(1)).[1] We consider the case in which the market for inputs needed to manufacture the product in the foreign country is competitive. In that case, the income allocated to the foreign country under the arm's-length standard is the amount that is needed to provide the foreign subsidiary with an after-tax rate of return equal to the cost of capital; the remainder (the residual profit) should be allocated to the domestic parent because the domestic firm provides the intellectual property from winning the patent race.

Enforcing the arm's-length standard, however, can pose problems because it may be difficult for the tax authority to value the intellectual property. This difficulty implies that, in practice, firms may be able to shift some of the taxable income that the intellectual property generates to a low-tax country by deviating from the arm's-length standard. Incentives to shift income can be strong because corporate statutory tax rates differ significantly across countries, ranging from 35 percent in the U.S. and 40 percent in Japan to 12.5 percent in Ireland and 17 percent in Singapore. Bartelsman and Beetsma (2003), Huizinga and Laeven (2008), and Clausing (2003) find evidence of income shifting away from high-tax countries to low-tax countries. In our model, we allow for the possibility that the multinational firm is able to shift some of the pretax residual profit to the foreign country by using an allocation of taxable income that is not consistent with the arm's-length standard. When the foreign tax rate is strictly less than the domestic tax rate, the firm's ability to deviate from the arm's-length standard increases the attractiveness of foreign production. When the firm complies with the arm's-length standard, it will optimally produce in the foreign country if either lower costs and/or a lower tax rate cause the residual profit from foreign production to be higher than the residual profit from domestic production. When the ability of the firm to deviate from the arm's-length standard is high, however, it may be optimal for the firm to produce in the foreign (low-tax) country even when the residual profit is greater when producing domestically.

---

[1] International coordination on the arm's-length standard has evolved over many years. The first Organization for Economic Co-operation and Development (OECD) model tax convention was enacted in 1958, but efforts to coordinate tax rules go back to efforts by the League of Nations in the 1920s.

We use our model to investigate the effect of taxation of intangible investments on the domestic government's tax collections. The traditional analysis of the taxation of intangible investments overstates the domestic government's tax collections on intangible investments because it ignores the tax deductions of the intangible investments of unsuccessful firms, and because it ignores the possibility that the tangible investment can be made in a foreign country. With free entry to the patent race, the project has zero after-tax net present value to the industry because firms optimally choose their investment levels such that, in present value terms, the industry-wide after-tax intangible investment cost equals the after-tax revenues generated by the successful investment. Because all investments in R&D are tax-deductible in the domestic country, this implies that the net present value of the domestic government's tax revenues associated with the *intangible investment* is zero if it gets to tax all the returns from the intangible investment, but strictly negative otherwise. In addition, the domestic government taxes the returns to the *tangible investment* only if this investment is made domestically. Therefore, the domestic government's tax revenues from the tangible and the intangible investment are strictly positive in case of domestic production, zero in case of foreign production with compliance with the arm's-length standard, and strictly negative in case of foreign production with deviations from the arm's-length standard.

We also investigate the effects of the level of the domestic tax rate on investments in R&D and domestic tax revenues. When production occurs domestically, a higher domestic tax rate increases the taxes collected on the successful firm's revenues in the production stage, but decreases the industry-wide level of investment in R&D, which delays the start of the production stage. The effect of a higher domestic tax rate on the present value of domestic tax revenues is therefore ambiguous, and depends on the effectiveness of the R&D process. In contrast, when production occurs in the foreign country, a higher domestic tax rate leads to more investment in R&D. This occurs because the entire investment in R&D is deducted at the domestic rate, but only part of the taxable income from the investment is taxed at the domestic rate. Hence, a higher domestic tax rate makes investment in R&D more attractive when production occurs in the foreign country. Because R&D investments generate weakly negative net present value tax revenues to the domestic government, a higher domestic tax rate unambiguously decreases the net present value of domestic tax revenues when production occurs in the foreign country.

We also use our model to investigate two ways in which taxation of intangible investments affects social welfare. Social welfare consists of the sum of firm value, the present value of taxes collected, and the present value of consumer surplus. Because taxes merely represent a redistribution of wealth, they do not directly affect social welfare. However, taxes indirectly affect social welfare through their effect on production and investment decisions. First, the taxation of intangible investments can affect the firm's choice of production location, which in turn affects social welfare. In our model, the firm's privately optimal production location is determined jointly by cost factors (fixed and variable production costs), the tax rates of the domestic and the foreign country, and the firm's ability to deviate from the arm's-length standard. Devereux and Griffith (1998) find that tax rate differentials have a significant effect on foreign investment decisions of U.S. multinationals; Hebous et al. (2011) find similar results with respect to foreign investment decisions by German multinationals. The socially optimal production location, however, is only driven by cost factors because taxes represent a wealth transfer, which does not affect the level of social welfare. Without tax rate differentials, the firm's privately optimal production location may not be socially optimal; therefore, a tax-induced choice of production location can increase social welfare.

Second, taxes affect social welfare indirectly because taxation affects the level of R&D investments in the first stage. We find that the privately optimal level of R&D investment is higher than the socially optimal level if the R&D process is relatively effective, and lower than the socially optimal level if the R&D process is relatively ineffective. We define effectiveness of R&D investments in terms of how quickly the winner of the race obtains the patent for a given level of investment. Because a higher domestic tax rate decreases the level of investment in R&D in case of domestic production, but increases the level of investment in R&D in case of foreign production, we find that whether a higher domestic tax rate moves the privately optimal investment level closer to or further away from the socially optimal level depends jointly on the production location and on the effectiveness of the R&D investments.

Overall, we find that the effects of taxation are ambiguous with respect to social welfare. The reason is that the equilibrium without taxes need not be efficient, for two reasons. First, Dasgupta and Stiglitz (1980) show that in a patent race, the privately optimal level of R&D investments could be inefficiently high or low. Second, we show that the privately optimal location of production could be socially inefficient, because the firm wants to maximize its own value, whereas social welfare also includes tax revenues and consumer surplus. Because the equilibrium without taxes need not be efficient, taxes could either increase or decrease efficiency, depending on the parameters of the model. This outcome is consistent with the theory of the second-best (Lipsey and Lancaster 1956).

In Section II we discuss prior literature. Section III presents the model. Section IV derives the privately optimal and socially optimal production location for the firm that wins the patent race. Section V derives the privately optimal and socially optimal investments in R&D, computes the net present value of the R&D investment for both the winner of the patent race and the industry as a whole, and investigates how taxes affect the level and efficiency of R&D investments. Section VI characterizes expected domestic tax collections. Section VII concludes.

II. PRIOR LITERATURE

Investments in Intangible Assets

Several papers in economics and accounting have focused on the tax-favored nature of investments in internally developed intangible assets. Fullerton and Lyon (1988) argue that effective tax rate measures that exclude the taxation of intangible capital are misleading. In an analysis restricted to investments in R&D and advertising, they estimate the effect of expensing these investments for the 1983 tax year. Dunbar and Sansing (2002) and Robinson and Sansing (2008) indirectly estimate investments in intangible assets based on the difference between a firm's book and market value of assets. All three papers find that the ability to expense investments in internally developed intangible assets significantly reduces the tax burden that corporations face by allowing the investment to be expensed when made, rather than being capitalized and amortized over the useful life of the asset. This paper extends this literature by considering the effects of developing the assets in one country and using them in another country.

Dasgupta and Stiglitz (1980) model a patent race in which there is free entry into the race, but only the first firm to make a discovery generates profits from the discovery. Free entry ensures that economic profits at the industry level are competed down to zero. They use their model to determine the socially optimal patent life and whether the privately optimal level of research is higher or lower than the socially optimal level. We use the Dasgupta and Stiglitz (1980) model to characterize the equilibrium level of investment in intellectual property. We extend their model by incorporating taxes into the analysis. We show that the effect of the domestic tax rate on the efficiency of R&D investments depends jointly on the production location and on the effectiveness of R&D investments.

Transfer Pricing Rules

Our study features a patent race in which the winner obtains valuable intellectual property. The tangible investment needed to use the intellectual property can be made either in the country in which the intellectual property is created or in a foreign country. The latter case raises the issue of transfer pricing because the owner of the intellectual property should be taxed on the value it adds. In the setting that we examine, 100 percent of the residual profit should be allocated to the domestic parent under the arm's-length standard, because the domestic firm provides the intellectual property from winning the patent race. The Comparable Profit Method (CPM), one of several transfer pricing methods prescribed by the United States Treasury Regulations interpreting Internal Revenue Code §482, achieves this outcome. Halperin and Srinidhi (1996) and Sansing (1999) both examine CPM in their studies of multinational taxation.

Our model allows for the possibility that firms may be able to shift some of the taxable income that the intellectual property generates to a low-tax country by deviating from the arm's-length standard. There is a large literature on the use of transfer pricing associated with intellectual property as a way of shifting taxable income from high-tax to low-tax countries. Intellectual property poses particularly difficult problems to tax authorities because it is difficult to value. Pearson (2008) reviews the challenges tax authorities face in this area. Grubert (2003) examines the relation between intangible assets generated by R&D investments and multinational taxation. He finds that about half of the income shifted from high-tax to low-tax countries is associated with R&D investments made by the parent corporation of a multinational enterprise. Similarly, Bartelsman and Beetsma (2003) find evidence of income shifting for OECD countries, particularly in industries such as pharmaceuticals with high levels of intellectual property. Huizinga and Laeven (2008) find evidence of income shifting by European multinationals away from high-tax Germany and toward European countries with lower tax rates. Clausing (2003) finds that when a U.S. multinational trades with a foreign affiliate in a country with a lower tax rate, intrafirm transfer prices are lower for exports by the parent and higher for imports by the parent, relative to transactions with unrelated parties. This is consistent with using transfer prices to shift income to the lower tax rate country.

Smith (2002) shows that the ability to deviate from the arm's-length standard, or *ex post* discretion, can enhance efficiency by acting as a substitute for inefficiently high investment in the low-tax country (*ex ante* discretion.) An important distinction is that Smith (2002) takes both upstream and downstream production location as exogenous, whereas we endogenize the location of production. Grubert and Slemrod (1998) find evidence of firms with high levels of intangible property, such as pharmaceuticals, choosing to manufacture in Puerto Rico to facilitate the shifting of income to a low-tax political jurisdiction. Grubert (2003) finds that R&D intensive multinational firms are likely to invest in countries with either very high or very low statutory tax rates, as the ability to shift income between political jurisdictions has the greatest benefit when the difference in the jurisdictions' statutory tax rates is high. Consistent with this evidence, in our model we find that the ability to shift income may induce the firm to produce in a low-tax foreign country. This can increase social welfare because social welfare includes tax revenues and consumer surplus, which the firm does not take into account when choosing where to produce. If the sum of consumer surplus and tax revenues is higher when production occurs in the low-tax country, then the tax-induced decision to produce there can increase social welfare.

III. MODEL

In this section, we develop a two-stage model in which firms engage in a patent race in stage one, and the winner of the race uses the patent to produce output in stage two. Tax considerations are important in each stage. Each firm gets to deduct its investment in R&D in the first stage, even though only the winner of the race will generate taxable income from the patent in the second stage. In the second stage, the winner of the race can produce in either its own country, or in a foreign country with a lower tax rate. The ability to shift taxable income to the low-tax country provides an incentive to produce in the foreign country.

The Patent Race

N identical firms compete for a patent by making an investment in R&D on date zero. Each firm can reduce the time it takes to obtain the patent by investing more in R&D. Specifically, in the absence of competitors, the time that it takes for firm i to obtain the patent is an exponentially distributed random variable $T_i \sim Exp(\eta_i \lambda)$, where η_i denotes firm i's investment in R&D and λ is the parameter reflecting the effectiveness of the search process. For any given investment level η_i, a higher value of λ implies that the expected time to obtain the patent decreases. Given that N firms compete, the patent will be obtained at time $T^* = \min\{T_i\}$. The firm that wins the patent will subsequently operate as a monopolist on a worldwide market, with an inverse demand function given by:

$$p(q) = \tilde{d} - \alpha q, \tag{1}$$

where $p(q)$ denotes the unit price, q denotes the quantity produced and sold, $\tilde{d}$ denotes a demand parameter, and α represents the sensitivity of price with respect to supply. To reflect variation in demand, we let $\tilde{d}$ be a random variable with mean μ and variance σ^2.

Net Present Value from Domestic and Foreign Production

The firm that wins the patent race then decides whether to produce domestically or in a foreign country. If the firm produces domestically, then it invests $K_D > 0$, which allows the firm to produce in perpetuity at a variable production cost of c_D per unit produced.[2] The investment could be a non-depreciable investment such as land; alternatively, it could be an investment in a physical plant that wears out over time, for which the variable production cost includes the amount needed to maintain its productive capacity.[3] Let:

$$\tilde{Y}_D = q_D[p(q_D) - c_D] = q_D[\tilde{d} - \alpha q_D - c_D] \tag{2}$$

denote the firm's annual taxable income from producing q_D units in the domestic country and selling them on the world market. Income from domestic production is taxed by the domestic government at a rate of τ_D. Future cash flows are discounted using the cost of capital r. Therefore, producing q_D units in perpetuity generates an expected after-tax net present value for the firm of:

---

[2] The perpetuity assumption simplifies the analysis; qualitatively similar results would arise if the firm's patent had a finite life.

[3] Under this interpretation, tax depreciation is equal to economic depreciation. Our results continue to hold in a qualitative sense as long as the investment K_D is not expensed for tax purposes when it is incurred.

$$V_D = (1-\tau_D)\int_0^{\infty} Y_D e^{-rt}dt - K_D = \frac{(1-\tau_D)\Pi_D}{r} \tag{3}$$

where $Y_D = E[\tilde{Y}_D]$, and where:

$$\Pi_D = Y_D - \frac{rK_D}{1-\tau_D} \tag{4}$$

denotes the expected annual residual profit from producing in the domestic country.

Alternatively, the firm can decide to produce in the foreign country F using a wholly owned subsidiary. If the firm produces in the foreign country, then it incurs a fixed cost of $K_F > 0$ and a variable production cost of c_F per unit produced. Let:

$$\tilde{Y}_F = q_F[p(q_F) - c_F] = q_F[\tilde{d} - \alpha q_F - c_F] \tag{5}$$

denote the firm's annual taxable income from producing q_F units in the foreign country and selling them on the world market. We let τ_F denote the foreign country's corporate tax rate. Because tax rate differentials are an economically important reason for firms to produce in a foreign country (see, e.g., Grubert 2003), we focus on the case in which the foreign country has a weakly lower tax rate, i.e., $\tau_F \leq \tau_D$. We let:

$$\Pi_F = Y_F - \frac{rK_F}{1-\tau_F} \tag{6}$$

denote the annual expected residual profit from producing in country F, where $Y_F = E[\tilde{Y}_F]$. Because production takes place in country F but the patent was developed in country D, both governments have the right to levy a tax on their share of the income. We assume that the transfer pricing method that the taxpayer uses allocates to the foreign subsidiary an amount of income that compensates it for its investment, yielding it an after-tax return on its investment equal to the cost of capital. The transfer pricing method allocates the remainder, the pretax residual profit, to the domestic and foreign countries in the proportions π and $1-\pi$, $0 \leq \pi \leq 1$. We discuss how π is determined in the next section. For any given value of π, the expected annual taxable income allocated to the foreign subsidiary equals:

$$\frac{rK_F}{1-\tau_F} + (1-\pi)\Pi_F. \tag{7}$$

The term $\frac{rK_F}{1-\tau_F}$ represents the taxable income allocated to the foreign subsidiary to compensate it for its investment of K_F; an allocation of pretax income of $\frac{rK_F}{1-\tau_F}$ ensures that the after-tax return is rK_F, which ensures that the subsidiary earns the market after-tax rate of return r on its investment of K_F. The income allocated to the domestic country equals π times the annual residual income. Because the fraction of income that is allocated to the domestic country for tax purposes is taxed at the domestic tax rate τ_D, and the fraction that is allocated to the foreign country is taxed at the rate τ_F, the expected after-tax net present value from producing q_F units in perpetuity in the foreign country becomes:

$$\begin{aligned} V_F &= (1-\tau_D)\int_0^{\infty}(\pi\Pi_F)e^{-rt}dt + (1-\tau_F)\int_0^{\infty}\left(\frac{rK_F}{1-\tau_F} + (1-\pi)\Pi_F\right)e^{-rt}dt - K_F \\ &= \frac{[1-(1-\pi)\tau_F - \pi\tau_D]\Pi_F}{r} = \frac{(1-\theta)\Pi_F}{r}, \end{aligned} \tag{8}$$

where:

$$\theta = (1 - \pi)\tau_F + \pi\tau_D \tag{9}$$

denotes the combined domestic and foreign tax rate on foreign income.

The expected net present value to the firm from producing in the foreign or in the domestic country, as given by (3) and (8), respectively, depends on the corresponding production quantities q_F and q_D. The firm first observes the realized demand parameter d, then determines the production quantity that maximizes the expected net present value of production. Solving the first-order conditions for (3) in case of domestic production, and for (8) in case of foreign production shows that the optimal production quantities in case of production in the domestic and in the foreign country, respectively, are given by:

$$q_D = \frac{\tilde{d} - c_D}{2\alpha} \text{ and } q_F = \frac{\tilde{d} - c_F}{2\alpha}. \tag{10}$$

Allocation of Taxable Income

The expected net present value to the firm from production in the foreign country depends on the proportion π of the residual profit that the transfer pricing method allocates to the domestic country for tax purposes. In this section, we discuss how π is determined. We assume that the governments agree upon transfer pricing regulations that are consistent with the arm's-length standard. The profit-split π used by the firm reflects both the arm's-length standard and the extent to which the firm manages to deviate from the arm's-length standard.

Although several transfer price methods are described in sections 1.482-2 through 1.482-6 of the U.S. Treasury Regulations, the "best method rule" determines which method is consistent with the arm's-length standard (Treas. Reg. §1.482-1(c)). We assume that there is a competitive market in the foreign country for the inputs needed to manufacture the product. In that case, the income allocated to the foreign country under the arm's-length standard is the amount that is needed to provide the foreign subsidiary an after-tax rate of return equal to the cost of capital; the remainder (the residual profit) should be allocated to the domestic parent because it provides the intellectual property from winning the patent race (Treas. Reg. §1.482-1(d)(4)(ii)(D)). This is true even if production can occur more cheaply in the foreign country. Therefore, the value of π that satisfies the arm's-length standard, π_{AL}, is 1. This allocation is consistent with the CPM, in which the foreign manufacturer is the "tested party" under Treas. Reg. §1.482–5(a)(2)(i). It is also consistent with residual profit-split method in the case in which the foreign manufacturer only provides routine contributions to the business activity, and the domestic parent provides the non-routine contributions of valuable intangible property (Treas. Reg. §1.482-6(c)(3)). In each case, the foreign subsidiary is allocated just enough taxable income to compensate it for its capital investment; the remainder is allocated to the domestic parent, because it provides the intangible asset that makes the residual profit possible. We emphasize that even when the foreign subsidiary receives no part of the residual profit (i.e., when $\pi = \pi_{AL} = 1$), it is compensated for its tangible investment, receiving payments with a pretax net present value of $\frac{K_F}{1-\tau_F}$. Specifically, when the firm complies with the arm's-length standard, the after-tax expected net present value for the foreign subsidiary from engaging in the transaction with the domestic parent is given by:

$$[\frac{K_F}{1 - \tau_F} + (1 - \pi_{AL})\left(\frac{\Pi_F}{r}\right)](1 - \tau_F) - K_F = 0.$$

Because the market in the foreign country is competitive, full compliance with the arm's-length standard implies that all of the residual profits are taxed by the domestic country, and the foreign subsidiary's investment of K_F is a zero net present value investment. When $\tau_F < \tau_D$, however, the firm has an incentive to deviate from the arm's-length standard; shifting part of the residual profit to the foreign country (i.e., $\pi < 1$) reduces its tax burden. We therefore allow for the case in which the profit-split π is strictly less than 1. The further that π is away from $\pi_{AL} = 1$, the greater is the ability of the multinational firm to deviate from the arm's-length standard.

IV. PRODUCTION LOCATION

In this section, we investigate the conditions that determine whether the firm will produce domestically or in the foreign country. We also investigate whether the privately optimal location decision is economically efficient. We focus on the case in which the patent has strictly positive value regardless of whether production takes place domestically or abroad, i.e., $\Pi_D > 0$ and $\Pi_F > 0$.

Privately Optimal Location Decision

The domestic parent will produce in the foreign country if that yields a higher expected net present value for the firm than producing in the domestic country. Combining (3) and (8) shows that the domestic parent will produce in the foreign country if and only if:

$$\frac{(1-\theta)\Pi_F}{r} = \frac{[1-(1-\pi)\tau_F - \pi\tau_D]\Pi_F}{r} > \frac{(1-\tau_D)\Pi_D}{r}. \tag{11}$$

We distinguish three cases. First, when $\Pi_F \geq \Pi_D$, it follows immediately from (11) that foreign production is optimal for all π because the residual profit from domestic production is lower, and it is taxed at a higher tax rate (i.e., $\tau_D \geq \theta$).

Second, when $\Pi_F \leq \left(\frac{1-\tau_D}{1-\tau_F}\right)\Pi_D$, domestic production is preferred for all π. To see why, first consider the case in which the residual profit from foreign production would be fully taxed at the lower foreign tax rate, i.e., $\pi = 0$ and so $\theta = \tau_F$. Then, $(1-\tau_F)\Pi_F < (1-\tau_D)\Pi_D$ and (11) imply that domestic production is preferred. Thus, domestic production is preferred even when the firm manages to have all of the residual profit from foreign production taxed at the lower foreign tax rate. An increase in π would make foreign production even less attractive because it increases the fraction of income that is taxed at the higher domestic tax rate (i.e., θ increases because π increases). Therefore, domestic production is preferred for all π.

Finally, if $\left(\frac{1-\tau_D}{1-\tau_F}\right)\Pi_D < \Pi_F < \Pi_D$, the firm's optimal production location depends on π. Equation (11) shows that foreign production is preferred to domestic production if and only if:

$$\pi < \pi^* = \frac{(1-\tau_F)\Pi_F - (1-\tau_D)\Pi_D}{(\tau_D - \tau_F)\Pi_F} \in (0,1). \tag{12}$$

Foreign production is optimal if the firm's ability to deviate from the arm's-length standard is sufficiently high (i.e., if π is sufficiently low). If the allocation of taxable income is consistent with the arm's-length standard (i.e., $\pi = 1$), then domestic production is preferred. This occurs because the residual profit from foreign production is lower ($\Pi_F \leq \Pi_D$), and the arm's-length standard implies that it is taxed at the domestic tax rate (i.e., $\pi = 1$ implies $\theta = \tau_D$). In contrast, when the firm can shift all of the residual profit to the low-tax country (i.e., $\pi = 0$ and so $\theta = \tau_F$), $\Pi_F(1-\tau_F) > \Pi_D(1-\tau_D)$ implies that producing in the foreign country is optimal. Therefore, even though the residual profit from foreign production is lower than the residual profit from domestic production, foreign production is optimal if the firm's ability to deviate from the arm's-length standard is sufficiently high. We summarize these results in Table 1.

Table 1 shows that the choice to produce in the foreign country can be driven by cost differentials, tax rate differentials, or the firm's ability to deviate from the arm's-length standard.

TABLE 1

Privately Optimal Production Location

Case	Production Location
I. $\Pi_F \le \left(\frac{1-\tau_D}{1-\tau_F}\right)\Pi_D$	Domestic for all π
II. $\left(\frac{1-\tau_D}{1-\tau_F}\right)\Pi_D < \Pi_F \le \Pi_D$	$\begin{cases}\text{Domestic if } \pi \ge \pi^* \\ \text{Foreign if } \pi < \pi^*\end{cases}$
III. $\Pi_F > \Pi_D$	Foreign for all π

When the firm complies with the arm's-length standard (i.e., $\pi = 1$), it will produce in the foreign country if either lower costs and/or a lower tax rate imply that the residual profit from foreign production is higher than the residual profit from domestic production, i.e., when $\Pi_F > \Pi_D$. However, if the firm is able to deviate from the arm's-length standard, then it may be optimal to produce in the foreign country even when that yields a lower residual profit, i.e., when $\Pi_F \le \Pi_D$. This is the case when the ability to deviate is sufficiently high (i.e., when $\pi < \pi^*$), and the residual profit from foreign production is not too low compared to the residual profit from domestic production (i.e., when $\Pi_F > \left(\frac{1-\tau_D}{1-\tau_F}\right)\Pi_D$).

Social Efficiency of Production Location

In this subsection, we examine whether the production location that maximizes the firm's after-tax profits is also optimal from a social welfare perspective as of date T^*, where T^* denotes the date on which the firm wins the patent race, and chooses whether to invest domestically or in the foreign country.

We first derive the socially optimal production location. Social welfare on date T^* from producing in country $i \in \{D, F\}$ consists of the sum of after-tax firm value, the present value of taxes collected, and the present value of consumer surplus. Equivalently, social welfare equals the difference between the value received by consumers and the social cost of production, all discounted back to date T^*. The value received by consumers (SV_i) is the area under the demand curve. It can be expressed as the present value of the sum of the amount paid by consumers, $p(q_i) \cdot q_i$, and consumer surplus, $\frac{\left(\tilde{d}-p(q_i)\right)\cdot q_i}{2}$, which equals:

$$SV_i = \frac{\left(\tilde{d} - p(q_i)\right) \cdot q_i}{2r} + \frac{p(q_i) \cdot q_i}{r}.$$

The social cost (SC_i) of production in country $i \in \{D, F\}$ is the sum of the fixed production cost when production commences, K_i, and the present value of future variable production costs, $\frac{c_i \cdot q_i}{r}$,

$$SC_i = \frac{c_i \cdot q_i}{r} + K_i.$$

Taking the difference between the gross social value and social cost of production during the production stage, and using the facts that $\left(p(q_i) - c_i\right) \cdot q_i = \tilde{Y}_i$, and $\tilde{d} - p(q_i) = \alpha q_i$, yields that the social welfare (S_i) of producing in country i is given by:

$$S_i = E\left[\frac{p(q_i) \cdot q_i}{r} + \frac{\left(\tilde{d} - p(q_i)\right) \cdot q_i}{2r} - \frac{c_i \cdot q_i}{r} - K_i\right] = E\left[\frac{\tilde{Y}_i}{r} + \frac{\alpha q_i^2}{2r} - K_i\right].$$

It follows from (2), (5), and (10) that $E[\alpha q_i^2] = E[\tilde{Y}_i]$. This yields the following expressions for the social value of producing domestically (S_D) and in the foreign country (S_F):

$$S_D = \frac{3Y_D}{2r} - K_D; \tag{13}$$

$$S_F = \frac{3Y_F}{2r} - K_F. \tag{14}$$

Therefore, domestic production is socially optimal if and only if:

$$\frac{3Y_D}{2r} - \frac{3Y_F}{2r} > K_D - K_F. \tag{15}$$

We now investigate whether the firm's preferred location also maximizes the social value of production. It follows from (11) that the firm produces in the domestic country if and only if:

$$\frac{(1-\tau_D)Y_D}{r} - \frac{(1-\theta)Y_F}{r} > K_D - \left(\frac{1-\theta}{1-\tau_F}\right)K_F. \tag{16}$$

The choice to produce in the foreign country can be driven by cost considerations (lower fixed and/or variable production costs), or by tax considerations (a lower θ due to a lower value of τ_F or the ability to deviate from the arm's-length standard). As can be seen from (15), the socially optimal production location is driven entirely by cost considerations because taxes are zero sum transfers.

We first consider the case in which there are no tax rate differentials, i.e., $\tau_F = \tau_D$, so that the firm's location choice is driven by cost considerations only. When $\tau_F = \tau_D$, it follows immediately from (16) that the firm produces in the foreign country if and only if:

$$\frac{(1-\tau_D)(Y_D - Y_F)}{r} > K_D - K_F. \tag{17}$$

Comparing (15) and (17) shows that the firm's privately optimal choice need not be socially optimal. For example, if:

$$\frac{(1-\tau_D)(Y_F - Y_D)}{r} < K_F - K_D < \frac{3(Y_F - Y_D)}{2r},$$

the firm will not produce in the foreign country even though it would be socially optimal to do so.

This implies that a tax-induced choice to produce in the foreign country can be welfare-improving. To illustrate this, we consider an example in which foreign production has lower variable costs but requires a higher initial investment. Let $Y_D = 175$, $Y_F = 232$, $K_D = 600$, and $K_F = 1200$. Moreover, let $r = 10$ percent. It follows from (13) and (14) that $S_D = 2025$ and $S_F = 2280$. Social welfare is maximized when production occurs in the foreign country because $S_F > S_D$.

Whether foreign production is optimal for the firm depends on the tax rates τ_D and τ_F, and on the firm's ability to deviate from the arm's-length standard, as measured by π. We let $\tau_D = 40$ percent. This implies that the residual profit from domestic production, Π_D, equals 75 (see (4)). We consider three levels of the foreign tax rate τ_F. In each case we determine the residual profit from foreign production Π_F from (6), and then use the results from Table 1 to determine the firm's privately optimal production location for all values of π. We display the results in Table 2. We first consider the case in which the foreign tax rate equals the domestic tax rate, i.e., $\tau_F = \tau_D = 40$ percent. The residual profit from foreign production, Π_F, equals 32, which is strictly lower than the residual profit from domestic production. Because the domestic and foreign tax rates are the same, Case I from Table 1 applies, and so the firm will choose to produce in the domestic country for all values of π. The firm's optimal choice does not depend on its ability to deviate

TABLE 2

Illustrations of Privately and Socially Optimal Production Locations

τ_F	Π_F	θ	Case from Table 1	Privately Optimal Location	Socially Optimal Location
40%	32	40%	I	Domestic for all π	Foreign
25%	72	$(1-\pi)25\% + \pi 40\%$	II	Domestic if $\pi \geq \frac{5}{6}$ Foreign if $\pi < \frac{5}{6}$	Foreign
20%	82	$(1-\pi)20\% + \pi 40\%$	III	Foreign for all π	Foreign

from the arm's-length standard in this case because $\tau_F = \tau_D = 40$ percent implies that the combined tax rate θ incurred in case of foreign production is 40 percent for any value of π. Thus, with equal tax rates, the firm chooses to produce in the domestic country, which is suboptimal from a social welfare perspective because social welfare is maximized when production occurs in the foreign country.

In contrast, when $\tau_F = 20$ percent (the bottom row in Table 2), $\Pi_F = 82$, which is higher than the residual profit from domestic production. Case III from Table 1 applies, and so the firm produces in the foreign country for all π. The firm's choice again does not depend on its ability to deviate from the arm's-length standard. Although the combined tax rate θ now does depend on π, the low value of the foreign tax rate induces the firm to make the socially optimal location choice (i.e., foreign production) for all π. Finally, suppose $\tau_F = 25$ percent, which implies that $\Pi_F = 72$, which is lower than the residual profit from domestic production. Case II from Table 1 applies. In this case, the difference between Π_D and Π_F is sufficiently small that the firm will produce in the foreign country if π is sufficiently low. It will produce in the foreign country if $\pi < \pi^* = 5/6$ (see (12)), and produce domestically if $\pi \geq 5/6$. Therefore, the firm's location choice will be socially optimal if and only if the ability to deviate from the arm's-length standard is sufficiently high.

To summarize, the results from Table 2 show that a tax-induced choice to produce in the foreign country, due to either a sufficiently low foreign tax rate (when $\tau_F = 20$ percent), or the ability to deviate from the arm's-length standard (when $\tau_F = 25$ percent and $\pi < 5/6$), can improve welfare because the more favorable tax treatment mitigates the fact that, absent the tax benefit, the firm's location choice would be socially suboptimal.

V. THE PATENT RACE

In this section, we first derive the firms' privately optimal levels of R&D investments, as well as the level of R&D investments that maximizes social welfare. We also analyze how taxes affect the level and social efficiency of R&D investments, and how these effects depend on the production location.

Privately Optimal Investment in R&D

The firm that wins the patent race at time T^* earns an expected net present value of V^*, where V^* depends on whether the firm produces in the domestic or in the foreign country. Specifically:

$$
\begin{aligned}
V^* &= \frac{(1-\tau_D)\Pi_D}{r}, \text{ in case of domestic production,} \\
&= \frac{(1-\theta)\Pi_F}{r}, \text{ in case of foreign production,}
\end{aligned}
\tag{18}
$$

where the conditions for domestic and foreign production are given in Table 1, and θ is given by (9).

We let W_i be a random variable that equals 1 if firm i wins the patent race, i.e., if $T_i = T^*$, and 0 otherwise. We assume that the search times, $T_1, \ldots, T_N$, are independent of the demand parameter $\tilde{d}$, so that T^* is independent of $\tilde{d}$. Then, the net present value of investing η_i in R&D for firm i is given by:

$$
\begin{aligned}
I_i &= E[e^{-rT^*}W_i]V^* - (1-\tau_D)\eta_i = V^*\left(\int_0^\infty e^{-rt}\eta_i\lambda e^{-\lambda t\sum_{j=1}^{N}\eta_j}dt\right) - (1-\tau_D)\eta_i \\
&= \left(\frac{\lambda\eta_i}{r+\lambda\sum_{j=1}^{N}\eta_j}\right)V^* - (1-\tau_D)\eta_i,
\end{aligned}
\tag{19}
$$

where V^* is given by (18).

The N firms engage in a patent race. Specifically, firm i invests η_i in search costs, where η_i maximizes the firm's net present value from investment in R&D, given the search costs $\eta_j, j \neq i$, of the other $N-1$ firms. As in Dasgupta and Stiglitz (1980), we assume that N is sufficiently large for the effect of a marginal change in η_i on aggregate search costs $\sum_{j=1}^{N}\eta_j$ to be negligible. The first-order condition for (19) is given by:

$$
V^*\lambda = (1-\tau_D)\left(r+\lambda\sum_{j=1}^{N}\eta_j\right). \tag{20}
$$

Because all firms are identical, this implies that the optimal amount of search cost for each firm equals:

$$
\eta_i = \eta^* = \frac{1}{N}\max\left\{\frac{V^*}{1-\tau_D} - \frac{r}{\lambda}, 0\right\}, \text{ for } i = 1, \ldots, N. \tag{21}
$$

The firms will engage in a patent race if λ, the effectiveness of the search process, is sufficiently high relative to the net present value of production for the firm that wins the patent, V^*. To ensure that the after-tax value of the patent is large enough so that firms will enter the patent race, we focus on cases in which tax rates are sufficiently low and λ sufficiently high so that $\eta^* > 0$. Because $\theta \leq \tau_D$, it follows from (18) and (21) that a sufficient condition for $\eta^* > 0$ is:

$$
\lambda > \max\left\{\frac{r^2}{\Pi_D}, \frac{r^2}{\Pi_F}\right\}. \tag{22}
$$

We conclude this subsection by characterizing the net present value of R&D investments for both the winner of the patent race and for the industry as a whole. We emphasize that we focus on all of the firms in an industry that try to develop intellectual property, rather than focusing only on the firm that succeeds. The following proposition shows that this has important implications for the net present value of investment in R&D:

Proposition 1:

(i) The net present value from investment in R&D to the winner is strictly positive, i.e.,

$$E[e^{-rT^*}]V^* - (1 - \tau_D)\eta^* > 0.$$

(ii) The net present value from investment in R&D at industry level is zero, i.e.,

$$E[e^{-rT^*}]V^* - (1 - \tau_D)\eta^* N = 0.$$

The above proposition shows that although the firm that wins the patent earns a strictly positive net present value, the net present value of investment in R&D is zero at the industry level. At the industry level, the quasi-rents associated with winning the patent race are competed away at the beginning of the race, at which point there are no barriers to entry. We will show in Section VI that this result has important implications for the present value of taxes collected by the domestic government.

How Taxes Affect R&D Investments

In this subsection, we show how the domestic tax rate affects the level of investment in R&D in the cases of domestic and foreign production.

Proposition 2:

(a) If production occurs in the domestic country, then η^* is strictly decreasing in τ_D;
(b) if production occurs in the foreign country, then η^* is strictly increasing in τ_D if $\pi < 1$, and is unaffected by τ_D if $\pi = 1$.

A higher domestic tax rate makes investment in R&D less attractive in the case of domestic production, but more attractive in the case of foreign production. The reason is as follows. A higher domestic tax rate decreases the firm's expected after-tax revenues in the production stage, and its after-tax costs in the patent race stage. In case of domestic production, the after-tax benefits decrease by more than the after-tax costs because the fixed production cost is not tax deductible. Therefore, a higher domestic tax rate makes investment in R&D less attractive to the firm in the case of domestic production. In contrast, in the case of foreign production, the fixed production costs are incurred by the foreign subsidiary. Because part of the revenues are taxed by the foreign country, but the investment in R&D is fully deductible at the domestic tax rate, a higher domestic tax rate makes investment in R&D more attractive in the case of foreign production.

Efficiency of R&D Investment

In this subsection, we investigate how the effect of the domestic tax rate on the efficiency of R&D investments depends on the production location. We first derive the socially optimal investment level. When η is invested in R&D, the discovery will occur on date $T(\eta) \sim Exp(\eta\lambda)$. When production occurs in country $i \in \{D, F\}$, the socially optimal level of investment maximizes the present value of the social value of producing in country i, minus the social investment costs, η, i.e., it solves:

$$\max_{\eta}\left\{S_i \cdot E[e^{-rT(\eta)}] - \eta\right\} = \max_{\eta}\left\{\left(\frac{\eta\lambda}{r + \eta\lambda}\right)S_i - \eta\right\},$$

for $i \in \{D, F\}$, where S_D and S_F are given in (13) and (14), respectively. Differentiating with respect to η yields a unique maximum at:

$$\eta_S = \sqrt{\frac{rS_i}{\lambda}} - \frac{r}{\lambda}, i \in \{D, F\}. \tag{23}$$

Consistent with Dasgupta and Stiglitz (1980), we find that the socially optimal investment level η_S could be higher or lower than the privately optimal industry-wide investment level $N\eta^*$. Investment could be inefficiently low (i.e., $N\eta^* < \eta_S$) because profit-maximizing firms do not consider the consumer surplus when choosing their investments in R&D. On the other hand, investment could be inefficiently high. Suppose, for example, that λ is very high. Then, the primary effect of a firm's investment in R&D is to increase that firm's chances of winning the patent race, without having a significant effect on the time until the discovery occurs. This results in socially inefficient overinvestment in R&D. We show when R&D investment is inefficiently high or low in Proposition 3.

Proposition 3: Investment in R&D is inefficiently high (low) if $\lambda > \lambda^*$ ($\lambda < \lambda^*$), where:

$$\lambda^* = \lambda_D^* = \frac{r^2(3Y_D - 2rK_D)}{2\Pi_D^2} \text{ if production occurs in the domestic country;}$$

$$\lambda^* = \lambda_F^* = \frac{r^2(3Y_F - 2rK_F)}{2\Pi_F^2}\left(\frac{1-\tau_D}{1-\theta}\right)^2 \text{ if production occurs in the foreign country.}$$

The proof is in Appendix A.

The above proposition shows that regardless of the production location, the privately optimal level of R&D investment is inefficiently high (low) if the R&D process is relatively effective (ineffective), where λ represents effectiveness. Combined with Proposition 2, however, this implies that how taxes affect the efficiency of R&D investments depends on production location. Combining Propositions 2 and 3 yields the following proposition:

Proposition 4:

(a) In the case of domestic production, an increase in the domestic tax rate induces less overinvestment in R&D if $\lambda > \lambda_D^*$, and more underinvestment if $\lambda < \lambda_D^*$.
(b) In the case of foreign production, an increase in the domestic tax rate induces more overinvestment if $\lambda > \lambda_F^*$, and less underinvestment if $\lambda < \lambda_F^*$.

In the case of domestic production, a higher domestic tax rate reduces investment in R&D and, therefore, reduces overinvestment if λ is sufficiently high, and leads to more underinvestment if λ is sufficiently low. In contrast, when production occurs in the foreign country, a higher domestic tax rate increases the level of investment in R&D and, therefore, leads to more overinvestment if λ is sufficiently high, and less underinvestment if λ is sufficiently low. We summarize the effects of the domestic tax rate on the level and efficiency of R&D investments in Table 3.

VI. DOMESTIC TAX REVENUES

Our focus in Sections IV and V was on whether the privately optimal decisions were also socially optimal. However, aggregate social welfare may not be the only concern of policymakers. In this section, we examine the present value of domestic tax revenues associated with the R&D investments and subsequent production by the winner of the patent race.[4] We also investigate how the effect of the domestic tax rate on domestic tax revenues depends on the production location.

---

[4] We limit our investigation to domestic corporate income taxes directly associated with the project. We do not speculate on whether other taxes would change, e.g., whether aggregate taxable labor income would increase due to the project, or instead be shifted from other activities.

TABLE 3

Effect of an Increase in τ_D on the Level and Efficiency of R&D Investment

Production Location	**Effect on the Level of R&D Investment**	**Effect on the Efficiency of R&D Investment**
Domestic production	Decreases	$\begin{cases}\text{Decreases if } \lambda < \lambda_D^* \\ \text{Increases if } \lambda > \lambda_D^*\end{cases}$
Foreign production with $\pi = 1$	No effect	No effect
Foreign production with $\pi < 1$	Increases	$\begin{cases}\text{Increases if } \lambda < \lambda_F^* \\ \text{Decreases if } \lambda > \lambda_F^*\end{cases}$

We first consider the present value of tax revenues received by the domestic government when production takes place domestically. The domestic government collects tax on the income earned from date T^* in perpetuity, and gives a tax deduction of η^* at time zero to each firm. Therefore, the net present value of the domestic government's tax revenues, X_D, equals:

$$X_D = \left[\frac{E[e^{-rT^*}]Y_D}{r} - \eta^* N\right]\tau_D. \tag{24}$$

We know from Proposition 1 that the net present value of investment in R&D is zero at the industry level. In case of domestic production, it follows from (18) that this implies that:

$$\eta^* N = \frac{E[e^{-rT^*}]\Pi_D}{r}. \tag{25}$$

Combining (24) and (25) shows that when production occurs in the domestic country, the net present value of taxes collected by the domestic government is given by:

$$X_D = \frac{E[e^{-rT^*}](Y_D - \Pi_D)\tau_D}{r} = \frac{E[e^{-rT^*}]K_D\tau_D}{1-\tau_D} > 0. \tag{26}$$

Even though the domestic government gives a deduction for the investment cost of all the firms that compete and collects tax only on the revenues of the winner, the net present value of taxes is strictly positive in case of domestic production. To see why, note that the domestic government collects taxes on the annual income Y_D as of date T^*, gives a tax deduction on date zero for the aggregate investment in R&D, $\eta^* N$, but does not give a tax deduction for the investment K_D on date T^*. Because the net present value of investment in R&D is zero at the industry level, the industry-wide deductible investment cost $\eta^* N$ equals the present value of the annual residual profit from production $\Pi_D = Y_D - \frac{rK_D}{1-\tau_D}$, which is strictly lower than annual taxable income Y_D. Therefore, the net present value of domestic tax collections is strictly positive in the case of domestic production. The domestic tax revenues are attributable to the normal return to capital from the tangible investment.

Next, we consider the tax revenues that the domestic government collects when production occurs in the foreign country. The domestic government collects tax on the fraction π of the residual profit Π_F from time T^* into perpetuity, and gives a tax deduction of η^* at time zero to each firm. Therefore, the present value of domestic government tax revenues is given by:

$$X_D = \left[\frac{E[e^{-rT^*}]\pi\Pi_F}{r} - \eta^* N\right]\tau_D. \tag{27}$$

Because the net present value of investment in R&D is zero at industry level (Proposition 1), it follows from (18) that:

$$\eta^* N = \frac{E[e^{-rT^*}]\left(\frac{1-\theta}{1-\tau_D}\right)\Pi_F}{r}. \tag{28}$$

Combining (27) and (28) shows that when production occurs in the foreign country, the net present value of taxes collected by the domestic government equals:

$$X_D = \frac{E[e^{-rT^*}]\left(\pi - \frac{1-\theta}{1-\tau_D}\right)\Pi_F \tau_D}{r} = \frac{E[e^{-rT^*}](\pi - 1)(1 - \tau_F)\Pi_F \tau_D}{r(1 - \tau_D)} \leq 0. \tag{29}$$

Comparing (26) and (29) shows that, in contrast to the case of domestic production, the net present value of domestic tax revenues in the case of foreign production is weakly negative. It is strictly negative when $\pi < 1$, and zero when $\pi = 1$. To see why, first consider the case in which the firm complies with the arm's-length standard, i.e., $\pi = \pi_{AL} = 1$. The foreign government taxes the normal return to capital on the tangible investment. The domestic country taxes 100 percent of the residual profit. Because industry-wide profits are zero, the deductible investment cost $\eta^* N$ equals the present value of the annual residual profit Π_F received as of date T^* (see Condition (28) with $\pi = 1$ so that $\theta = \tau_D$). Thus, if the firm complies with the arm's-length standard, then the present value of taxes collected on the revenues from production equals $\tau_D \eta^* N$, and so the net present value of domestic tax collections is zero. When the firm is able to deviate from the arm's-length standard, i.e., when $\pi < \pi_{AL} = 1$, the net present value of domestic tax revenues is strictly negative because the domestic country gives a tax deduction for the full investment cost, but collects taxes on only part of the residual profits.

We summarize the above results in the following proposition:

Proposition 5:

(a) If production occurs in the domestic country, then the net present value of domestic tax revenues is strictly positive; and
(b) if production occurs in the foreign country, then the net present value of domestic tax revenues is weakly negative; it is zero under the arm's-length standard, and strictly negative when the firm is able to deviate from the arm's-length standard.

The above proposition shows that when production takes place in the low-tax country, deviating from the arm's-length standard causes the present value of taxes collected by the domestic government to be strictly negative. As we illustrated in Table 2, it is possible that deviating from the arm's-length standard enhances social welfare. Therefore, deviating from the arm's-length standard has countervailing effects on domestic tax revenues and social welfare in this case.

Next, we investigate how the effect of the domestic tax rate on the present value of domestic tax revenues depends on the production location. First, consider the case of domestic production. A higher domestic tax rate has a direct effect on tax collections in the two stages. In addition, a higher domestic tax rate also affects domestic tax revenues indirectly through its effect on the amount invested in R&D. We know from Proposition 2 that a higher domestic tax rate reduces the amount invested in R&D. This affects domestic tax revenues in two ways. First, it decreases the level of the deductible investment costs. Second, it decreases the present value of tax revenues in the production stage by delaying the expected date T^* at which the patent race ends and production begins.

Now consider the case in which production takes place in the foreign country. We know from Proposition 2 that a higher level of τ_D in this case implies that more is invested in R&D. Therefore, a higher domestic tax rate not only increases the taxes collected on the income allocated to the domestic country, but also increases their present value by decreasing the expected date at which production starts. In addition, it increases both the level of the deductible investment cost and the tax rate that applies to the deduction.

In the following proposition we show that in the case of foreign production, the increase in the present value of tax revenues in the production stage is less than the decrease in tax revenues in the patent race stage, and so a higher domestic tax rate unambiguously decreases the net present value of domestic tax revenues. In the case of domestic production, the effect of a higher domestic tax rate is ambiguous, and depends jointly on the level of the domestic tax rate and the effectiveness of the R&D process, as measured by the parameter λ.

Proposition 6:

(a) If production occurs in the domestic country, then there exists a critical value $\bar{\lambda} > 0$ such that:

   (i) if $\lambda < \bar{\lambda}$, then there exists a critical value τ_D^* such that an increase in τ_D increases the net present value of domestic tax revenues if $\tau_D < \tau_D^*$, and decreases the net present value of domestic tax revenues if $\tau_D > \tau_D^*$;

   (ii) if $\lambda > \bar{\lambda}$, then an increase in τ_D increases the net present value of domestic tax revenues.

(b) If production occurs in the foreign country, an increase in τ_D decreases the net present value of domestic tax revenues if $\pi < 1$, and has no effect on the net present value of domestic tax revenues if $\pi = 1$.

Combined with Proposition 2, the above proposition implies that in the case of foreign production, a tax-induced increase in the level of R&D investments due to a higher domestic tax rate unambiguously decreases the net present value of taxes collected by the domestic government. In contrast, in the case of domestic production, the effect of a tax-induced increase in the level of R&D investments due to a lower domestic tax rate depends on the effectiveness of the R&D process.

VII. CONCLUSIONS

We examine the effects of taxes on investments in intellectual property in a setting in which the property can be developed in one country and used in another country. We develop a two-stage model in which a large number of firms engage in a patent race in stage one; in stage two, the winner of the patent race produces in either the domestic country, in which the property was developed, or in a foreign country, which has a lower tax rate.

The location decision of the firm that wins the patent race depends on the production costs, the tax rates, and the allocation of taxable income. Deviating from the arm's-length standard can cause a multinational to produce in a low-tax foreign country in a setting in which the firm would produce domestically if the allocation of taxable income were consistent with the arm's-length standard. This tax-induced shift in the location of production can be welfare improving. Weaker enforcement of the arm's-length standard may therefore improve aggregate social welfare, even though it reduces domestic tax revenues.

We also show how the effects of taxation on R&D investments depend on whether production takes place domestically or in a foreign country. First, a higher domestic tax rate decreases R&D investments in the case of domestic production, but increases R&D investments in the case of foreign production. Second, the privately optimal level of R&D investment could be higher or lower than the socially efficient level. Whether a higher domestic tax rate moves the privately optimal investment level closer to or further away from the socially optimal level depends jointly on the production location and on the effectiveness of the R&D investments, i.e., how quickly the patent is obtained for a given level of investment.

Finally, we show the effect of the production location on the domestic government's tax collections. We find that the present value of taxes collected by the domestic government is weakly negative if production occurs in the foreign country and strictly positive if production occurs domestically. In addition, a higher domestic tax rate unambiguously decreases the net present value of domestic tax revenues when production occurs in the foreign country, but has ambiguous effects on the present value of domestic tax revenues in the case of domestic production.

APPENDIX A

Proof of Proposition 1

At the industry level, the net present value of investment in R&D is given by:

$$I_{industry} = \sum_{i=1}^{N} I_i = E[e^{-rT^*}]V^* - (1 - \tau_D)\eta^* N. \tag{30}$$

Conditional on winning the patent race, the winning firm earns an *NPV* of:

$$I_{winner} = E[e^{-rT^*}]V^* - (1 - \tau_D)\eta^*.$$

It follows from (21) that the expected discount factor is given by:

$$E[e^{-rT^*}] = \int_0^\infty e^{-rt} N\lambda\eta^* e^{-N\lambda\eta^* t} dt = \frac{N\lambda\eta^*}{r + N\lambda\eta^*} = 1 - \frac{(1 - \tau_D)r}{\lambda\ V^*}. \tag{31}$$

This implies that:

$$I_{industry} = 0, \text{ and that } I_{winner} = I_{industry} + (1 - \tau_D)\eta^*(N - 1) > 0.$$

This concludes the proof.

Proof of Proposition 2

(a) If domestic production is optimal, then:

$$V^* = \frac{(1 - \tau_D)\Pi_D}{r}, \eta^* = \frac{1}{N}\left[\frac{\Pi_D}{r} - \frac{r}{\lambda}\right], \text{ and } \frac{\partial\eta*}{\partial\tau_D} = -\frac{K_D}{N(1 - \tau_D)^2} < 0.$$

(b) If foreign production is optimal, then:

$$\eta^* = \frac{1}{N}\left[\frac{(1 - \theta)\Pi_F}{r(1 - \tau_D)} - \frac{r}{\lambda}\right] = \frac{1}{N}\left[\frac{\left(1 - \pi\tau_D - (1 - \pi)\tau_F\right)\Pi_F}{r(1 - \tau_D)} - \frac{r}{\lambda}\right].$$

Differentiation shows that $\frac{\partial\eta*}{\partial\tau_D} \geq 0$, with a strict inequality when $\pi < 1$.

Proof of Proposition 3

Follows immediately from comparing $N\eta*$ and η_S, where $N\eta*$ follows from Equations (18) and (21), and η_S follows from (13), (14), and (23).

Proof of Proposition 6

(a) We first determine the range of values of τ_D for which domestic production is optimal. If domestic production is optimal for some value of τ_D, then it is optimal for all smaller values of τ_D, i.e., there exists a τ_D^{ind} such that domestic production is optimal if $\tau_D \leq \tau_D^{\text{ind}}$.

Differentiating X_D from Equation (24) with respect to τ_D and simplifying yields:

$$sign\left[\frac{\partial X_D}{\partial\tau_D}\right] = sign\left[\Pi_D^2 - \frac{r^2}{\lambda}(Y_D - rK_D)\right].$$

The right-hand side is decreasing in τ_D. It follows from (22) that $\lambda > \frac{r^2}{\Pi_D} \geq \frac{r^2}{(Y_D - rK_D)}$. For any $\lambda > \frac{r^2}{(Y_D - rK_D)}$, it holds that:

$$\Pi_D^2 = (Y_D - rK_D)^2 > \frac{r^2}{\lambda}(Y_D - rK_D), \text{ for } \tau_D = 0,$$

$$\Pi_D^2 = 0 < \frac{r^2}{\lambda}(Y_D - rK_D), \text{ for } \tau_D = \tau_D^{\max},$$

where $\tau_D^{\max}$ is such that $\Pi_D = 0$ for $\tau_D = \tau_D^{\max}$. Therefore, $\frac{\partial X_D}{\partial \tau_D}$ has a unique root $\tau_D^*(\lambda) \in [0, \tau_D^{\max}]$, and $\frac{\partial X_D}{\partial \tau_D} > 0$ for $\tau_D < \tau_D^*(\lambda)$, and $\frac{\partial X_D}{\partial \tau_D} < 0$ for $\tau_D > \tau_D^*(\lambda)$. The root $\tau_D^*(\lambda)$ is strictly increasing in λ. Moreover, it holds that:

$$\lim_{\lambda \to \infty} \tau_D^*(\lambda) = \tau_D^{\max},$$
$$\lim_{\lambda \to [r^2/(Y_D - rK_D)]} \tau_D^*(\lambda) = 0.$$

Because $\Pi_D = 0$ for $\tau_D = \tau_D^{\max}$, and $\Pi_F > 0$, foreign production is optimal when $\tau_D = \tau_D^{\max}$. This implies that $\tau_D^{ind} \in [0, \tau_D^{\max})$. Therefore, there exists a $\bar{\lambda} \in [\frac{r^2}{(Y_D - rK_D)}, \infty)$ such that $\tau_D^*(\bar{\lambda}) = \tau_D^{ind}$. We distinguish two cases:

- if $\lambda > \bar{\lambda}$, then it holds that $\tau_D^*(\lambda) > \tau_D^{ind}$. Therefore, when domestic production is optimal, i.e., when $\tau_D \leq \tau_D^{ind}$, it holds that $\tau_D < \tau_D^*(\lambda)$ so that $\frac{\partial X_D}{\partial \tau_D} > 0$.
- If $\lambda < \bar{\lambda}$, then it holds that $0 \leq \tau_D^*(\lambda) \leq \tau_D^{ind}$, and an increase in the domestic tax rate increases the present value of domestic tax revenues if $\tau_D \leq \tau_D^*(\lambda)$, but decreases the present value of domestic tax revenues if $\tau_D \geq \tau_D^*(\lambda)$.

(b) Next, we consider the case of foreign production. An increase in the domestic tax rate increases η^*, which implies that $E[e^{-rT^*}]$ increases. Because $\frac{\tau_D}{1-\tau_D}$ is increasing in τ_D, it holds that:

$$E[e^{-rT^*}]\frac{(1-\pi)(1-\tau_F)\tau_D}{(1-\tau_D)},$$

is a product of nonnegative increasing terms, and is therefore increasing in τ_D. It therefore follows immediately from (29) that X_D is weakly decreasing in τ_D, and is strictly decreasing in τ_D if $\pi < 1$.

Do Managerial Incentives Drive Cost Behavior? Evidence about the Role of the Zero Earnings Benchmark for Labor Cost Behavior in Private Belgian Firms

ABSTRACT: This study investigates the influence of managerial incentives to meet or beat the zero earnings benchmark on labor cost behavior of private Belgian firms. We posit that relative to managers of firms reporting healthy profits, managers meeting or beating the zero earnings benchmark will increase labor costs to a smaller extent when activity increases and decrease labor costs to a larger extent when activity decreases. This should take the form of more symmetric labor cost behavior for firms that report a small profit. Our findings are consistent with this prediction. Using detailed employee data, we show that managers of firms reporting a small profit focus on firing employees who are relatively low cost to fire. To protect their reputation in the labor market, managers of other firms, particularly those reporting healthy profits, limit the numbers of dismissals and react to activity changes by changing the number of hours that employees work.

I. INTRODUCTION

Traditional cost models assume that variable costs change symmetrically and proportionally with changes in activity levels. Recent empirical research, however, documents asymmetry in cost behavior in which costs increase more rapidly with an activity increase than they decrease with an activity decrease (Anderson et al. 2003; Balakrishnan et al. 2004). Anderson et al. (2003) and Noreen and Soderstrom (1997) suggest that asymmetric cost behavior arises because managers make rational decisions as they trade off the costs of resource adjustments against the costs of keeping slack resources. It can also arise because managers perceive the costs of downward adjustments to be higher than those of upward adjustments.

Although managerial behavior can be an important driver of cost asymmetry, empirical evidence about this conjecture is only beginning to emerge. The few studies that exist generally use aggregate data for publicly traded U.S. firms, making it difficult to address how specific costs are managed. In particular, because these studies often rely on aggregate proxies for discretionary costs, such as selling, general, and administrative costs, it is difficult to infer which managerial decisions lead to variations in cost behavior. In addition, because managers of publicly traded firms often face a more complex array of incentives than those faced by managers of private firms, it is more difficult to infer whether specific managerial incentives affect how particular costs are managed.

In this study, we examine whether and how managerial incentives to meet or beat the zero earnings benchmark affect cost behavior in private Belgian firms, resulting in predictable differences in the degree of labor cost asymmetry for firms that do and do not face the benchmark. The unique institutional setting of this study provides us with several advantages relative to studies that examine cost behavior in publicly traded U.S. firms. First, private Belgian firms must disclose disaggregated cost information, including total labor costs, number of employees, and total number of hours worked. These data enable us to study cost behavior for labor cost, which is commonly the largest expense on the income statement. Furthermore, having specific information regarding the components of labor cost, including number of employees, number of hours worked, and the composition of the labor force, i.e., number of blue-collar workers and number of white-collar workers, permits us to examine which specific actions managers take when managing labor costs. Second, because managers of private Belgian firms have unusually strong incentives to avoid losses for reasons we explain more fully below, we have a powerful setting in which to study how the incentive to meet or beat the specific zero earnings benchmark affects discretionary decisions regarding labor costs. Third, studying cost behavior in private Belgian firms mitigates certain issues of potential goal incongruence between managers and shareholders that arise in publicly traded firms. This enables us to make predictions of how the managerial incentive to meet or beat the zero earnings benchmark affects discretionary labor costs with limited contamination from the effects of shareholder-manager agency costs.

Two characteristics of the Belgian institutional environment motivate the importance of the zero earnings benchmark. First, meeting the zero earnings benchmark determines whether private Belgian firms are allowed to pay dividends to the owners and cash bonuses to the managers. Second, auditors are required to issue a going-concern opinion when Belgian firms report a loss during two consecutive years, and this opinion often results in bank intervention. Because debt financing of private firms in Belgium is heavily bank-oriented, firms have an interest in avoiding a going-concern opinion and have strong incentives to report a profit in the year following a reported loss. Given the importance of the zero earnings benchmark for private Belgian firms, we posit that the incentive to meet or beat the zero earnings benchmark increases the costs of upward resource adjustments and decreases the costs of downward resource adjustments. Hence, managers who want to avoid a loss will be more willing to cut labor costs when sales decrease and to limit the increase in labor costs when sales increase. As a result, we expect the incentives to meet or beat the zero earnings benchmark to offset the forces that lead to asymmetric cost behavior. This leads us to predict that, relative to other firms, firms that just meet the zero earnings benchmark will exhibit a more symmetric labor cost pattern.

Because private Belgian firms are required to disclose detailed information about the composition of their workforce and their employee decisions in their publicly available financial statements, studying labor cost behavior in private Belgian firms enables us to gain insights regarding managerial decisions in response to activity changes in two different ways. First, the detailed data allow us to measure empirically the richness in managerial responses to activity changes and whether managers react differently when facing the zero earnings benchmark. Adapting labor costs to activity changes can affect the number of hours each employee works or the number of individuals the firm employs. Given the high costs associated with firing employees, including severance costs and loss of reputation in the labor market, we expect that only managers facing a strong need for immediate cost reduction, particularly managers who require cost adjustments to meet or beat the zero earnings target, will fire employees in response to activity decreases.

Second, we examine whether managers take into account variations in severance costs of employees when adjusting their labor costs. Belgium is an ideal institutional setting to investigate this issue because Belgian labor law draws a strict distinction with respect to termination provisions between blue-collar and white-collar workers. Blue-collar workers receive shorter notice of termination compared to white-collar workers, and redundancy payments are lower when dismissing blue-collar workers compared to white-collar workers.[1] Therefore, firing blue-collar workers is a relatively low-cost means to realize immediate cost reductions and should be utilized more frequently by firms facing incentives to meet or beat the zero earnings benchmark.[2]

Using a sample of 37,880 firm-year observations over the period 1995–2006, we first document significant labor cost asymmetry for a broad cross-section of private Belgian firms. A 1 percent increase in revenues leads to a 0.60 percent increase in labor costs, and a 1 percent decrease in revenues is associated with a 0.34 percent decrease in labor costs. We next provide evidence supporting our key hypothesis that firms that just meet or beat the zero earnings benchmark exhibit less cost asymmetry relative to other firms. That is, they spend less on resources in response to sales increases and hoard fewer resources in response to sales decreases. To further examine the role of earnings targets on cost behavior, we partition our sample into different subsamples. Subsample analysis indicates that firms that just meet or beat the zero earnings benchmark actually exhibit cost symmetry, i.e., the change in labor costs in response to an activity change does not differ between an activity increase and activity decrease. In contrast, firms that report a small loss or a large profit experience cost asymmetry. We also test our hypothesis by restricting our sample to observations relating to those firms that meet or beat the zero earnings benchmark at least once during our sample period. We find that these firms exhibit a more symmetric cost pattern only in the years that they report a small profit. Our results are robust to the inclusion of a control for the amount of accrual-based earnings management and other control variables. Collectively, these results provide support for the hypothesis that firms that meet or beat the zero earnings benchmark limit the increase in labor costs when activity increases and are more willing to cut labor costs when activities decrease.

---

[1] The redundancy payment typically consists of the salary that the employee would have earned during the period of notice. Although the period of notice depends upon the seniority of the employee, the period of notice of a blue-collar worker is at most four weeks while the period of notice of a white-collar worker is at least three months.

[2] Because blue-collar workers are easier and cheaper to fire, firms have tried to exploit this characteristic of blue-collar workers to manage labor costs during the recent economic crisis. For example, the Belgian division of the U.S. firm Brink's, a firm that provides global security services such as cash handling, proposed changing the contracts of the employees responsible for cash transportation from a white-collar contract to a blue-collar contract to increase the firm's flexibility with respect to labor costs. Brink's management contends that this change is necessary to save the firm from bankruptcy because firing a large number of white-collar workers would saddle the firm with so much additional cost that the firm would be forced into bankruptcy (*De Standaard*, January 12, 2011).

Next, we examine the underlying managerial decisions for the observed cost patterns and find that managerial decisions are consistent with economic incentives. Specifically, when faced with decreasing sales, firms that report a healthy profit reduce the number of hours that employees work rather than the number of employees. In contrast, firms that report a small profit are more likely to terminate blue-collar workers who are the least costly to fire. These findings are consistent with small-profit firms facing a more immediate need to cut labor costs and being less concerned about loss of reputation in the labor market.

Our study extends the asymmetric cost literature in two ways. First, we present evidence that variations in cost behavior are driven by managerial incentives. Although Chen et al. (2012) and Kama and Weiss (2010) consider the impact of managerial incentives on cost behavior, these studies do so in a setting in which there is a clear separation between ownership and decision-making. In contrast, we examine the influence of managerial incentives on cost behavior in private firms. Although public and private firms share common objectives, such as avoiding the violation of debt covenants, private firms are not exposed to the disciplining force of the capital markets, thereby making it easier to infer whether specific managerial incentives affect how particular costs are managed. Second, our analysis of detailed employee data illuminates how managers behave when adjusting labor costs and shows that variations in cost asymmetry are driven by different managerial decisions. This analysis emphasizes the link between the literature on the use of real activities to meet earnings benchmarks and the literature on asymmetric cost behavior.

This remainder of this paper is organized as follows. Section II discusses the relevant literature and develops the hypotheses. Section III describes the research method. Section IV discusses the findings and provides a number of sensitivity analyses.

II. LITERATURE OVERVIEW AND HYPOTHESES

Cost Asymmetry

Traditional cost accounting models assume that variable costs change proportionally and symmetrically with changes in the activity driver, regardless of the direction of the activity change (e.g., Noreen 1991). In contrast, models of asymmetric cost behavior postulate that managers influence resource adjustments, resulting in asymmetric cost behavior. To the extent that managers perceive that adjustment costs are greater for a downward adjustment than for an upward adjustment, costs will fall less with activity decreases than they will rise with activity increases.

Recent large-sample empirical evidence documents asymmetric cost behavior. Anderson et al. (2003) find that selling, general, and administrative (SG&A) costs increase on average by 0.55 percent for a 1 percent increase in sales but decrease only by 0.35 percent for a 1 percent decrease in sales. Anderson et al. (2003) also show that the degree of cost asymmetry depends on the expected level of adjustment costs, which varies systematically across firms and over time.

Anderson et al. (2003) have stimulated research in the area of cost asymmetry along three dimensions. A first area examines the link between variables that influence adjustment costs and the degree of cost asymmetry (e.g., Balakrishnan et al. 2004; Calleja et al. 2006). A second area addresses the moderating influence of structural factors on the degree of cost asymmetry (e.g., Banker and Chen 2006; Balakrishnan and Gruca 2008). A third, less explored area involves the impact of managerial incentives on cost asymmetry. Chen et al. (2012) investigate managerial empire-building incentives as a determinant of cost asymmetry. The study finds that empire-building incentives are positively related to the degree of cost asymmetry and that good corporate governance mitigates this relationship. Kama and Weiss (2010) examine the influence of incentives to meet earnings targets and technological constraints on cost asymmetry in listed U.S. firms. Our study extends this third line of research by examining the influence of incentives to meet or beat the zero earnings benchmark on cost asymmetry of labor costs in private Belgian firms. By focusing on discretionary labor costs in this unique institutional setting, we are able to shed light on the underlying managerial decisions to change costs in response to activity changes.

Earnings Management

A large number of studies examine the reasons why firms manage their earnings (e.g., Burgstahler and Dichev 1997; Degeorge et al. 1999). The evidence shows that firms manage earnings to avoid small losses and earnings decreases, to meet analysts' earnings forecasts, to avoid breaching debt covenants, or to show a smooth earnings pattern. Most of the evidence in these studies relates to publicly traded firms that face the disciplining force of capital markets, although some of the objectives are common to private firms, such as avoiding violation of debt covenants.

The literature identifies two main strategies to manage reported earnings: (1) accrual-based earnings management that does not affect cash flows and (2) real actions that affect cash flows. Recent research has focused on how firms manage earnings by manipulating real activities (e.g., Roychowdhury 2006; Gunny 2010). For example, Roychowdhury (2006) shows that firms use real activities to meet financial reporting targets, such as providing price discounts to temporarily boost sales, reducing discretionary expenditures to improve reported margins, and overproducing to lower the cost of goods sold. Other studies document that managers cut strategic investments, such as R&D investments, to meet earnings targets (Baber et al. 1991; Garcia Osma and Young 2009).

Cost Asymmetry and Earnings Management in Private Belgian Firms

One important real earnings management tool is managing labor costs. Indeed, labor costs are subject to managerial discretion and represent a significant cost to the firm, especially for private firms (Anderson and Lanen 2007).[3] Furthermore, relative to investments in fixed or other tangible assets, investments in employees are generally more divisible and reversible, although they may have other costs, including hiring and firing costs, loss of reputation in the labor market, and reduced morale for the remaining employees (Pindyck 1988). In other words, firms will adjust labor costs when the benefits of doing so outweigh the associated costs. We posit that the zero earnings benchmark provides managers with particularly strong incentives to manage labor costs.

The zero earnings benchmark is an important benchmark for private Belgian firms for several reasons. First, meeting or beating the zero earnings target helps to avoid violating debt covenants and to prevent banks from intervening in the management of the firm (Kamin and Ronen 1978; Danos et al. 1989; Graham et al. 2005). Second, reporting a positive profit not only conveys an important signal to other stakeholders, such as employees and suppliers (Bowen et al. 1995; Burgstahler and Dichev 1997), but also is a necessary legal condition for Belgian firms to be able to pay dividends to owners and cash bonuses to managers. Finally, when Belgian firms report a loss in two consecutive years, the external audit firm must issue a going-concern opinion, which can damage the firm's creditworthiness. Taken together, private Belgian firms have numerous reasons to avoid reporting a loss, which is consistent with previous research documenting that private Belgian firms manipulate accruals to avoid reporting a loss (Coppens and Peek 2005).

We hypothesize that private Belgian firms will manage labor costs to avoid reporting a loss. In particular, Belgian firms will be more willing to cut labor costs when sales decrease and less willing to increase labor costs when sales increase if these actions enable firms to avoid reporting a loss. If so, then the results should include a lower degree of cost asymmetry, i.e., a more symmetric cost pattern, in firms that meet or beat the zero earnings benchmark (hereafter, small-profit firms) compared to other firms.

---

[3] For many businesses, especially those in the service industry, such as restaurants, or manufacturing firms that are labor intensive, labor costs are the largest line item on the income statement. In our sample, on average 27 percent of total revenues is spent on labor costs, ranging from 8 percent to almost 87 percent.

> **H1:** Small-profit firms exhibit a lower degree of labor cost asymmetry, i.e., *ceteris paribus*, they exhibit a reduced response to sales increases and an increased response to sales decreases.

Mechanisms for Adjusting Labor Costs

Firing employees imposes various costs on Belgian firms, including redundancy payments, loss of morale of the remaining employees, and loss of reputation in the labor market. As a result, managers of firms that report a large profit (hereafter, large-profit firms) are less likely to dismiss employees when faced with an activity decrease. These termination costs lead to our prediction that large-profit firms will change the number of employees asymmetrically in response to changes in activity levels. They will increase the number of employees more when activity levels increase than they will decrease the number of employees when activity levels decrease. Rather than firing employees, managers of large-profit firms are more likely to reduce the number of hours that employees work when faced with an activity decrease. Thus, we predict the number of hours per employee to decrease more when activity levels decrease than they increase when activity levels increase. In activity-increasing periods, large-profit firms will meet labor needs by hiring workers rather than by increasing the number of hours per employee.

In contrast, managers of firms seeking to avoid reporting a loss are less concerned about costs such as loss of morale of the remaining employees and loss of reputation in the labor market and, therefore, are more likely to revert to measures that result in significant cost reductions, such as employee dismissals. As a result, we predict that managers of small-profit firms will adjust both the number of employees and the number of hours per employee symmetrically in response to changes in activity levels.

Because large-profit firms are less likely to fire employees in response to activity declines, we predict that the number of blue-collar and white-collar workers will exhibit similar asymmetric changes in response to activity changes. In contrast, we predict that small-profit firms will dismiss employees, particularly blue-collar workers, to manage their labor costs. Thus, for small-profit firms, we predict that the number of blue-collar workers will exhibit symmetric changes in response to activity changes, but the number of white-collar workers will exhibit asymmetric changes.[4]

III. METHOD

Sample Selection

We obtain our sample from the Bel-First database of Bureau Van Dijk, which consists of all Belgian firms that are unlisted and have at least 50 employees.[5] Our sample covers the years 1993 through 2006 and consists of 51,826 firm-year observations. Table 1, Panel A, describes how we construct our final sample. As in Anderson et al. (2003) and Chen et al. (2012), we require labor costs and sales revenues to be available in the current and previous year and labor costs to be less

---

[4] Our prediction depends on whether the labor cost savings from firing one higher paid white-collar worker relative to one blue-collar worker is sufficiently smaller than the relatively smaller redundancy costs for blue-collar workers. However, because the period of notice and redundancy payments for the white-collar workers are substantially larger than those for blue-collar workers, white-collar workers should be fired earlier in the fiscal year to be beneficial for managing earnings upward. Because managers prefer to have good information regarding the firm's expected financial performance before taking any action and such information becomes clearer later in the fiscal year, we predict that blue-collar workers are more susceptible to be fired to meet or beat the zero earnings benchmark.

[5] By requiring firms to have at least 50 employees, we eliminate small firms from the sample. These firms are not required to have their financial statements audited.

TABLE 1

Sample Selection

Panel A: Full Sample

	Number of Firm-Years
Potential Sample[a]	51,826
Less: Observations with missing data on either sales revenue or labor costs for the current or preceding year	(9,051)
Less: Observations for which labor costs exceed sales revenue for the current year	(324)
Less: Observations from listed firms	(535)
Less: Observations with missing data on other variables	(3,190)
Less: Trim top and bottom of change in sales and change in labor costs at 0.5 percent level	(846)
Final Sample	37,880

Panel B: Distribution of Firm-Year Observations over Sample-Years

Sample-Year	Large-Loss Sample	Small-Loss Sample	Small-Profit Sample[b]	Large-Profit Sample	Full Sample
1995	486	162	515	1,821	2,984
1996	469	172	551	1,802	2,994
1997	420	148	497	1,959	3,024
1998	436	138	476	1,959	3,009
1999	515	141	451	1,953	3,060
2000	524	158	455	1,918	3,055
2001	645	168	454	1,801	3,068
2002	675	188	481	1,769	3,113
2003	450	112	252	1,694	2,508
2004	600	146	304	2,568	3,618
2005	619	116	297	2,665	3,697
2006	539	135	334	2,742	3,750
Total	6,378	1,784	5,067	24,651	37,880

[a] Firms need to satisfy two criteria in order to be included in the sample: they should be unlisted and have at least 50 employees. We obtain this sample from the Bel-first database of Bureau Van Dijck over the period 1993–2006.

[b] We label "small-profit" firm-years as those relating to firm-years for which net income scaled by total assets is greater than or equal to 0 but less than 1 percent (Roychowdhury 2006). "Small-loss" firm-years are those firm-years for which net income scaled by total assets is smaller than 0 but greater than −1 percent. "Large-profit" firm-years are all profitable firm-years that are not "small-profit" and "large-loss" firm-years are all loss-making firm-years that are not "small-loss."

than sales. Also, following Chen et al. (2012), we delete observations for which changes in sales and labor costs are in the top and bottom 0.5 percent. This results in a final sample of 37,880 firm-year observations between 1995 and 2006.[6]

Following prior research, we define firms suspected of managing their earnings to meet or beat the zero earnings benchmark as consisting of firm-year observations for which the net income as a percentage of beginning-of-year total assets is larger than or equal to zero but smaller than 1 percent (Roychowdhury 2006; Cohen et al. 2008). This is our so-called *small-profit* sample. Our *large-*

---

[6] Because we require sales data to be available for the two prior years, we lose observations from 1993 and 1994.

profit sample includes all other firm-year observations that report a profit. We classify firm-years that fall in the area immediately to the left of zero as *small-loss* observations, i.e., firm-year observations for which the net income as a percentage of beginning-of-year total assets is less than zero but greater than −1 percent. We classify all other loss-making firm-year observations as *large-loss* observations. Table 1, Panel B, presents the distribution of the firm-year observations over the sample-years for the full sample and various subsamples.

Model Specification and Variable Definitions

Asymmetry of Labor Costs

To test for labor cost asymmetry, we use models similar to those in Anderson et al. (2003). The basic model is given by Equation (1):

$$\log\left(\frac{LaborC_{it}}{LaborC_{it-1}}\right) = \beta_0 + \beta_1 \log\left(\frac{Sales_{it}}{Sales_{it-1}}\right) + \beta_2 Decrease\_Dummy_{it} * \log\left(\frac{Sales_{it}}{Sales_{it-1}}\right) + \varepsilon_{it}, \tag{1}$$

where $LaborC_{it}$ denotes labor costs of firm i in year t; $Sales_{it}$ are sales revenues; and $Decrease\_Dummy_{it}$ is an indicator variable set equal to 1 when sales in year t are smaller than sales in year t–1, and 0 otherwise.

The coefficient, β_1, is the percentage increase in labor costs for a 1 percent increase in sales; the sum of β_1 and β_2 represents the percentage decrease in labor costs for a 1 percent decrease in sales. Based on prior literature, we expect β_1 to be positive, β_2 to be negative, and the absolute value of β_1 to be greater than the absolute value of β_2 for the full sample of private Belgian firm-years. To control for error dependence of firm observations, we use Rogers (1993) standard errors clustered at the firm level in all regressions (Petersen 2009).

Compared to the basic model, the extended model given by Equation (2) includes controls for economic determinants of cost asymmetry identified in prior research (Anderson et al. 2003; Pinnuck and Lillis 2007) and the extent of accrual-based earnings management:

$$\begin{aligned}
\log\left(\frac{LaborC_{it}}{LaborC_{it-1}}\right) = {} & \beta_0 + \beta_1 \log\left(\frac{Sales_{it}}{Sales_{it-1}}\right) + \beta_2 Decrease\_Dummy_{it} * \log\left(\frac{Sales_{it}}{Sales_{it-1}}\right) \\
& + \beta_3 Abnor\_Accruals_{it} * \log\left(\frac{Sales_{it}}{Sales_{it-1}}\right) \\
& + \beta_4 Decrease\_Dummy_{it} * \log\left(\frac{Sales_{it}}{Sales_{it-1}}\right) * Successive\_Decrease_{it} \\
& + \beta_5 Decrease\_Dummy_{it} * \log\left(\frac{Sales_{it}}{Sales_{it-1}}\right) * Employee\_Intensity_{it} \\
& + \beta_6 Decrease\_Dummy_{it} * \log\left(\frac{Sales_{it}}{Sales_{it-1}}\right) * Asset\_Intensity_{it} \\
& + \beta_7 Decrease\_Dummy_{it} * \log\left(\frac{Sales_{it}}{Sales_{it-1}}\right) * Economic\_Growth_{t} \\
& + \beta_8 Decrease\_Dummy_{it} * \log\left(\frac{Sales_{it}}{Sales_{it-1}}\right) * Loss\_Prior\_Year_{it} \\
& + \beta_9 Decrease\_Dummy_{it} * \log\left(\frac{Sales_{it}}{Sales_{it-1}}\right) * Abnor\_Accruals_{it} \\
& + \beta_{10} Successive\_Decrease_{it} + \beta_{11} Employee\_Intensity_{it} \\
& + \beta_{12} Asset\_Intensity_{it} + \beta_{13} Economic\_Growth_{t} + \beta_{14} Loss\_Prior\_Year_{it} \\
& + \beta_{15} Abnor\_Accruals_{it} + \varepsilon_{it}.
\end{aligned} \tag{2}$$

Successive_Decrease equals 1 if sales have decreased in two consecutive years (i.e., $Sales_{t-2} > Sales_{t-1} > Sales_t$), and 0 otherwise. *Employee_Intensity* is the ratio of total number of employees over sales, while *Asset_Intensity* is the ratio of total assets over sales. *Economic_Growth* is growth in real GNP in year *t*. *Loss_Prior_Year* indicates whether the firm reported, or did not report, a loss in the prior year. All other variables are as previously defined. We include the economic determinants as main terms and as three-way interaction variables to model their moderating behavior with regard to decreases in sales. Based on prior research, we do not expect these variables to have an impact on increases in sales and therefore we do not include them in a two-way interaction with the log of the sales ratio.[7]

In addition to the economic determinants used in prior literature, we include a control for the amount of accrual-based earnings management (*Abnor_Accruals*) because managers can also manipulate accruals to meet or beat the zero earnings benchmark. We use the DeFond and Park (2001) model as adapted by Francis and Wang (2008) and include signed abnormal accruals as a main term and add two- and three-way interaction terms. Prior research documents that real and accrual-based earnings management are negatively correlated (Zang 2012; Cohen and Zarowin 2010), which suggests that firms that manipulate their accruals more can manage their labor costs less. On the other hand, if firms want to meet or beat the zero earnings benchmark, then they can use both mechanisms to avoid reporting a loss. Therefore, we make no predictions with regard to the sign of the coefficients on variables relating to abnormal accruals.

Cost Asymmetry and Incentives to Report a Small Profit

We use three approaches to investigate whether small-profit observations exhibit a lower degree of labor cost asymmetry. First, we add to Equation (2) an indicator variable, *Small_Profit*, which equals 1 for firm-year observations that report a small profit and 0 otherwise, and include two-way ($Small\_Profit * \text{Log}\,(Sales_{it}/Sales_{it-1})$) and three-way ($Small\_Profit * Decrease\_Dummy * \text{Log}\,(Sales_{it}/Sales_{it-1})$) interaction terms. This permits Equation (2) to be estimated using the entire sample while permitting coefficients to differ for small-profit and other firms. Specifically, the two-way (three-way) interaction term represents the difference in labor cost increase (decrease) following an activity increase (decrease) of small-profit firms relative to other firms. We predict a significantly negative coefficient on the two-way interaction term, i.e., small-profit firms will have a smaller increase in labor costs for a 1 percent increase in sales. We also predict a significantly positive coefficient on the three-way interaction term, i.e., small-profit firms will have a larger decrease in labor costs for a 1 percent decrease in sales.

Second, we use split-sample regressions, i.e., we estimate the basic and extended model separately for the small-profit, large-profit, and small-loss samples. We do not estimate regressions for firms with large losses, because such firms are likely to restructure or to manage earnings using "big bath" accounting, reflecting one-time charges against income, which makes it difficult to compare their cost behavior with that of other observations. We predict small-profit firms will exhibit more cost symmetry than large-profit firms. In comparison to large-profit observations, we predict β_1 to be smaller and β_2 to be less negative or insignificantly different from zero for small-profit observations. That is, firms that seek to meet or beat the zero earnings benchmark and that face an increase (decrease) in sales, will increase (decrease) labor costs to a smaller (larger) extent than large-profit firms. Our expectations for the small-loss observations are less clear because small-loss observations could include observations relating to firms that attempted to report a small profit but did not succeed or observations relating to firms that do not have incentives to report a small profit. Although the former group should exhibit a cost pattern similar to that of small-profit observations, the latter group should exhibit an asymmetric cost pattern. Given the heterogeneity of the small-loss sample, we therefore expect a more symmetric cost pattern for the small-profit sample compared to the small-loss sample.

---

[7] Nonetheless, we also estimated Equation (2) including two-way interaction terms in the regression models. However, because the inclusion of all two-way interaction terms simultaneously leads to multicollinearity and spurious regression results, we include the two-way interactions terms separately in sequential estimations of Equation (2). Untabulated findings result in inferences identical to those in the tabulated results.

In a third test, we restrict our sample to observations of firms that have reported a small profit at least once during the period 1995–2006. As with the extended model regressions, we predict a significantly negative coefficient on the two-way interaction term, i.e., small-profit firm-years will have a smaller increase in labor costs for a 1 percent increase in sales relative to non-small-profit firm-years, and a significantly positive coefficient on the three-way interaction term, i.e., small-profit firm-years will have a larger decrease in labor costs for a 1 percent decrease in sales relative to non-small-profit firm-years. An advantage of this third analysis is that each firm serves as its own control, thereby mitigating the effects on our inferences in unmodeled differences in firm characteristics between small-profit and large-profit firms.

IV. RESULTS

Descriptive Results

Table 2 provides descriptive statistics for the different subsamples. Because our analyses focus on comparisons of large-profit and small-profit firms, we describe only the summary statistics for these subsamples. On average, the large-profit observations have sales revenues of €54,792,680 and labor costs of €9,023,870. In comparison, the small-profit firm-years have on average lower sales revenues and labor costs, €46,247,380 and €8,662,690. The average ratio of labor costs to sales revenues is 26 (27) percent for the large-profit (small-profit) subsample, indicating that labor costs are an important cost category for both sets of firms. The average number of employees is almost 200 for both subsamples. Mean beginning-of-year total assets is lower for the large-profit observations, €53,308,310 versus €75,187,500, versus for small-profit observations. Table 2 also reveals that large-profit observations have a lower probability of a decrease in sales, 27 percent versus 36 percent for small-profit observations, a lower probability of a successive decrease in sales, 9 percent versus 12 percent, and a lower probability of having recorded a loss in the previous year, 11 percent versus 21 percent. Abnormal accruals do not differ significantly across the subsamples. Finally, untabulated statistics reveal no significant differences with regard to the distribution across industries between the different samples.[8]

Results of Hypothesis Tests

Asymmetry of Labor Costs

Columns I and II of Table 3 present the regression summary statistics for the basic and extended models, Equations (1) and (2), for the full sample of 37,880 firm-year observations. The results of the basic model show significant labor cost asymmetry in private Belgian firms with $\beta_1 = 0.64$ ($t = 19.44$) and $\beta_2 = -0.22$ ($t = -4.47$). After controlling for other determinants of cost asymmetry by means of the extended model, we still find significantly asymmetric labor costs ($\beta_1 = 0.60$, $t = 15.93$; $\beta_2 = -0.26$, $t = -3.66$). Hence, an increase in sales revenues of 1 percent leads to an

---

[8] As a robustness check, we add industry indicators to all estimated regressions. Untabulated findings reveal that none of the inferences differ from those relating to tabulated results.

This table presents descriptive statistics for the full sample and subsamples over the period 1995–2006. See Table 1 for definitions of the subsamples.

Variable Definitions:
LaborC = labor costs;
Sales = sales revenue;
Change_LaborC = change in labor costs between year *t* and year *t*–1;
Change_Sales = change in sales between year *t* and year *t*–1;
Relative_Change_LaborC = ratio of change in labor costs between year *t* and year *t*–1 to beginning total assets of year *t*;
Relative_Change_Sales = ratio of change in sales between year *t* and year *t*–1 to beginning total assets of year *t*;
LaborC/Sales = ratio of labor costs to sales revenue;
Number_of_Employees = number of employees in year *t*;
Beginning_Total_Assets = total assets of year *t*–1;
Decline_Observations = percentage of observations with a decrease in sales revenue between year *t* and year *t*–1;
Successive_Decrease = 1 when $Sales_{t-2} > Sales_{t-1} > Sales_t$, and 0 otherwise;
Employee_Intensity = ratio of total number of employees to sales revenue;
Asset_Intensity = ratio of total assets to sales revenue;
Economic_Growth = growth in real gross national product (GNP);
Loss_Prior_Year = 1 when the firm reports a loss in the previous year, and 0 otherwise; and
Abnor_Accruals = signed abnormal accruals following Francis and Wang (2008).

increase in labor costs of 0.60 percent, while a decrease in sales revenues of 1 percent results in a decrease in labor costs of 0.34 percent.

With regard to the control variables, we find no significant effect of a successive decrease in sales ($\beta_6 = -0.00$, t = –0.01), asset intensity ($\beta_8 = 0.00$, t = 0.14), economic growth ($\beta_9 = -0.01$, t = –0.28) and loss prior year ($\beta_{10} = 0.05$, t = 1.16). Firms with a higher employee intensity exhibit a lower degree of cost asymmetry ($\beta_7 = 4.27$, t = 4.87). Abnormal accruals have no effect on cost asymmetry ($\beta_4 = 0.02$, t = 0.31; $\beta_{11} = 0.02$, t = 0.18).[9]

Cost Asymmetry and Incentives to Report a Small Profit

Our primary prediction is that firms reporting a small profit exhibit a lower degree of labor cost asymmetry. More specifically, we predict that small-profit observations will exhibit a smaller labor cost increase following an activity increase and a larger labor cost decrease following an activity decrease, both of which induce the overall pattern of labor cost symmetry.

Table 3, Column III, presents findings from the first test of this hypothesis, which is based on estimating Equation (2) including the small-profit indicator variable and associated interaction terms. Consistent with our predictions, we find a significantly negative coefficient on the two-way interaction term ($\beta_3 = -0.26$; t = –2.83) and a significantly positive coefficient on the three-way

---

[9] The labor cost elasticities for sales increases and decreases are for a firm with zero values for the control variables, i.e., ignoring the interactive effect of the control variables on sales. For a firm with median values of the control variables, we still find clear evidence of cost asymmetry. In particular, for the median firm, an increase in sales revenues of 1 percent leads to an increase in labor costs of 0.60 percent, while a decrease in sales revenues of 1 percent results in a decrease in labor costs of 0.25 percent.

[d] The model used is similar to the model used in Column III. The restricted sample consists of firm-year observations relating to firms that have reported a small profit at least once during the period 1995–2006.

See Table 2 for variable definitions.

interaction term ($\beta_5 = 0.34$, $t = 2.77$). In comparison to firms that do not report a small profit, the labor cost increase of small-profit firms for a 1 percent increase in sales is 0.26 percent smaller and the labor cost decrease of small-profit firms for a 1 percent decrease in sales is 0.34 percent larger.[10]

Table 4 presents the result for our split sample tests, which are conducted by estimating the basic and extended models separately for the large-profit and small-profit observations. Findings for the large-profit sample are similar to those of the full sample. Specifically, we find strong evidence for asymmetric cost behavior of large-profit firm-year observations for the basic model ($\beta_1 = 0.64$, $t = 14.94$; $\beta_2 = -0.24$, $t = -3.77$) as well as for the extended model ($\beta_1 = 0.62$, $t = 12.18$; $\beta_2 = -0.16$, $t = -5.48$). Consistent with our predictions, small-profit observations exhibit symmetric labor cost behavior for the basic model ($\beta_1 = 0.41$, $t = 4.86$; $\beta_2 = 0.10$, $t = 0.89$) and for the extended model ($\beta_1 = 0.43$, $t = 6.36$; $\beta_2 = -0.12$, $t = -0.90$). Furthermore, the increase in labor costs following an activity increase is significantly smaller for small-profit observations compared to large-profit observations ($F = 350.83$; p-value < 0.01).[11] Taken together, results for the split-sample regressions provide additional support for the hypothesis that firms manage their labor costs to meet or beat the zero earnings benchmark, which results in symmetric labor cost behavior.

Table 3, Column IV, presents findings from the third test of our primary hypothesis in which we estimate Equation (2), limiting our sample to those observations of the firms that have reported a small profit for at least one year during the period 1995–2006. Although this test reduces our sample to 20,516 firm-year observations, we still find support for our hypothesis. In particular, the coefficient on the two-way interaction term is significantly negative ($\beta_3 = -0.13$; $t = -1.87$) and the coefficient on the three-way interaction is significantly positive ($\beta_5 = 0.27$; $t = 1.94$).[12]

Taken together, the findings in Tables 3 and 4 provide consistent support for our primary hypothesis by showing that small-profit observations exhibit symmetric labor cost behavior while large-profit observations exhibit asymmetric labor cost behavior.[13,14]

---

[10] Estimating Equation (2) including the small-profit indicator variable and associated interaction terms for a sample of firms that includes only small-profit firms and large-profit firms leads to the same inferences. Specifically, we find a significantly negative coefficient on the two-way interaction ($\beta_3 = -0.25$, $t = -2.52$) and a significantly positive coefficient on the three-way interaction ($\beta_5 = 0.30$, $t = 2.26$). The coefficients relating to large-profit firms' activity increases and decreases, β_1 and β_2, are consistent with such firms exhibiting cost asymmetry ($\beta_1 = 0.62$, $t = 12.04$, and $\beta_2 = -0.22$, $t = -2.36$).

[11] The F-test is based on the combined sample of small-profit and large-profit firm-year observations.

[12] Excluding the firm-years in which a loss is reported leads to the same inferences. Specifically, we find a significantly negative coefficient on the two-way interaction term ($\beta_3 = -0.13$; $t = -1.92$) and a significantly positive coefficient on the three-way interaction term ($\beta_5 = 0.26$; $t = 1.97$).

[13] Untabulated findings from estimations of the different models that include a control for firm size (i.e., the natural logarithm of the beginning-of-year total assets) indicate that inferences are unchanged. To facilitate comparisons with prior literature, we tabulate the results from estimations of the regression models that are used in prior literature.

[14] To mitigate the effect of other differences between small-profit observations and large-profit observations on labor cost behavior, we also conducted all of our analyses using a matched-sample design comprising a set of small-profit firms (i.e., treatment firms) and large-profit firms (i.e., matched firms). Specifically, we matched small-profit and large-profit firm-year observations using propensity scores that are estimated separately for each sample year. The first stage of the propensity score matching analysis is a logistical regression that includes variables to predict whether a firm reports a small profit, specifically whether a firm experiences a successive yearly income decrease, beginning-of-year asset intensity, beginning-of-year employee intensity, loss prior year, auditor type as Big N-auditor or not, industry, the natural logarithm of the beginning-of-year total assets, and abnormal accruals. We then assign a matched firm to each treatment firm based on predicted propensity scores that insignificantly differ according to paired t-tests. Untabulated findings from estimations of the different regression models on a sample that includes the treatment and matched firm-years result in no change in inferences relative to tabulated findings.

Mechanisms of Adjusting Labor Costs

In this section, we present results from tests that use detailed employee data to examine the mechanisms that managers of private Belgian firms use to manage their labor costs to meet or beat the zero earnings benchmark. Because Belgian firms have been required to disclose detailed employee data only since 1997, the sample of 21,552 firm-year observations, which we refer to as the "Employee-Detail" sample, is approximately one-third smaller than the sample available for prior tests. We also eliminate observations that have missing values for at least one of the variables required to conduct the tests presented in this section. Untabulated descriptive statistics for the Employee-Detail sample are comparable to those of the full sample. Inferences from the previous section do not change when we estimate the basic and extended model on the Employee-Detail sample.

Table 5 presents findings from estimations of the extended model with number of hours per employee and number of employees as the dependent variable. The models analyze how managers adjust the number of employees by firing and hiring employees, and/or adjust the number of hours per employee in response to activity changes. The results generally suggest that managers of small-profit firms prefer the former strategy of adjusting the number of employees, and managers of large-profit firms prefer the latter strategy of adjusting the number of hours worked by each employee. In particular, small-profit firm-years exhibit a symmetric pattern for the number of employees ($\beta_1 = 0.25$, t = 4.26; $\beta_2 = 0.06$, $t = 0.33$) and for the number of hours per employee ($\beta_1 = 0.09$, t = 2.53; $\beta_2 = 0.04$, t = 0.43). In contrast, large-profit firm-years exhibit asymmetry with respect to the number of employees ($\beta_1 = 0.41$, t = 11.34; $\beta_2 = -0.28$, t = −3.72) and with respect to number of hours per employee ($\beta_1 = 0.19$, t = 5.42; $\beta_2 = 0.09$, t = 1.92), although the positive β_2 implies that the number of hours per employee *decreases* more with an activity decrease than it increases with an activity increase. In addition, the number of hours per employee is more sensitive to activity changes for large-profit firm-years, i.e., an increase (decrease) of 0.19 percent (0.28 percent) following a 1 percent increase (decrease) in activity, than for small-profit observations, i.e., a change of 0.09 percent following a 1 percent change in activity.

Taken together, the findings in Table 5 provide support for our prediction that the asymmetric cost pattern of large-profit observations is driven by managerial decisions to avoid employee dismissals when activity decreases and to react to activity decreases by changing the number of

$$

See Table 2 for variable definitions.

hours per employee. In contrast, managers of small-profit firms do so by making decisions that result in immediate cost reductions, i.e., by firing employees.

Table 6 reports findings from estimations of the extended model using the number of white-collar and blue-collar workers as the dependent variables. These estimations compare the decisions regarding white-collar and blue-collar workers for large-profit and small-profit firm-years. Consistent with our predictions and consistent with the findings for the number of employees reported in Table 5, the findings in Table 6 indicate asymmetric behavior for both number of white-collar workers ($\beta_1 = 0.39$, $t = 8.47$; $\beta_2 = -0.26$, $t = -2.73$) and for the number of blue-collar workers ($\beta_1 = 0.39$, $t = 7.59$; $\beta_2 = -0.20$, $t = -2.42$) for large-profit observations. In contrast, small-profit observations exhibit symmetric behavior for white-collar workers ($\beta_1 = 0.17$, $t = 2.65$; $\beta_2 = 0.02$, $t = 0.15$). For blue-collar workers, the number increases 0.21 percent following a 1 percent increase in activity, but decreases 0.68 percent following a 1 percent decrease in activity ($\beta_1 = 0.21$, $t = 2.83$; $\beta_2 = 0.47$, $t = 3.89$). These results indicate that whereas differences in severance costs do not play a role for large-profit firms, managers of small-profit firms focus on the type of employees that can be fired in the cheapest way, i.e., blue-collar workers.

Small-Loss Firms

As noted above, small-loss firms could potentially have faced similar incentives as small-profit firms, but were unable to meet the zero earnings benchmark. If this is the case, then we expect small-loss observations to exhibit similar cost behavior as small-profit firms. Table 7 presents findings for small-loss firms analogous to those presented for large-profit and small-profit firms in Tables 4 to 6. Findings for estimations based on total labor costs appear to contradict the expectation that small-loss observations face similar incentives as small-profit observations, as small-loss observations exhibit cost asymmetry for the basic model ($\beta_1 = 0.68$, $t = 8.04$; $\beta_2 = -0.30$, $t = -2.52$) and for the extended model ($\beta_1 = 0.72$, $t = 8.94$; $\beta_2 = -0.55$, $t = -3.51$). However, findings from estimations based on the number of employees, the number of hours per employee, and the number of blue-collar workers indicate that they respond in a symmetric way to activity changes ($\beta_1 = 0.38$, $t = 4.47$; $\beta_2 = -0.17$, $t = -1.11$ for the number of employees; $\beta_1 = 0.25$, $t = 3.14$; $\beta_2 = -0.41$, $t = -1.62$ for the number of hours per employee; $\beta_1 = 0.38$, $t = 3.79$; $\beta_2 = -0.16$, $t = -0.45$ for the number of blue-collar workers). Surprisingly, the number of white-collar workers increases following an activity decrease ($\beta_1 = 0.27$, $t = 2.11$; $\beta_2 = -0.46$, $t = -2.13$), and likely accounts for the difference in total labor cost behavior between small-loss observations and small-profit observations.

See Table 2 for variable definitions.

Additional Analyses and Sensitivity Testing

In this section we consider several additional tests to determine the sensitivity of our findings regarding symmetry of labor costs for small-profit firms to an alternative measure of accruals-based earnings management, the time difference between real and accrual-based earnings management, the flexibility to manage labor costs, operational difficulties, and future growth prospects.

First, we repeat our analyses measuring the amount of accrual-based earnings management using the performance-adjusted Modified Jones (1991) model. Although doing so reduces the sample to 16,122 firm-year observations, untabulated findings from estimations of the extended model and split sample regressions indicate that inferences are unchanged because when we use this alternative measure of abnormal accruals, small-profit (large-profit) firms exhibit cost symmetry (asymmetry). Next, to mitigate the potential effects arising from the time difference between real and accrual-based earnings management, we replace our *ex post* measurement of the amount of accrual-based earnings management with two *ex ante* measures. The first is the presence of a Big N auditor, measured by an indicator variable that equals 1 if the firm is audited by a Big N auditor, and 0 otherwise. The second is the extent of accounting flexibility (Zang 2012; Cohen and Zarowin 2010; Gunny 2010), which we measure as net operating assets as a fraction of total assets (Barton and Simko 2002). We expect the presence of a Big N auditor to increase the cost of using accrual-based earnings management. Accounting flexibility to manipulate accruals is constrained by the extent to which a firm has used accrual-based earnings management in the past because most accruals reverse in the current period (Barton and Simko 2002; Hirshleifer et al. 2004). Untabulated findings from estimations of the extended model and split sample regressions that include each of these *ex ante* variables indicate that inferences are unchanged.

Our findings can also be influenced by a firm's flexibility to manage labor costs. Because blue-collar workers can be more easily fired in Belgium, firms with a greater proportion of blue-collar workers can more easily manage their labor costs. Consequently, we expect labor costs to behave more symmetrically for firms with a greater proportion of blue-collar workers. Untabulated findings of the extended model and split sample regressions reveal that small-profit firms with more flexibility to manage labor costs indeed have more symmetric cost behavior, but the proportion of blue-collar workers has no effect on the cost behavior of large-profit firms.

Operational difficulties could also contribute to the difference in labor cost behavior between small-profit and large-profit firms. We expect firms with operational difficulties to increase labor costs less in response to an activity increase and decrease labor costs more in response to an activity decrease. We measure operational difficulties using two proxy variables, the ratio of cash and cash flow to total assets, and by including the quick ratio, the change in quick ratio, and a measure of the probability of bankruptcy based on Altman (1968). Untabulated findings relating to the estimation of the extended model and split sample regressions with these controls for operational difficulties do not change our inferences.

Finally, cost asymmetry can arise because managers react to private information regarding the extent to which an activity change is temporary or permanent. Prior studies typically use economic growth and successive activity decreases to capture the manager's estimation of persistence of the activity change (Anderson et al. 2003). However, because these variables may not sufficiently capture firm-level future prospects, the differences in cost asymmetry we observe between small-profit and large-profit observations can be driven by insufficient controls for future prospects. Specifically, weak future prospects can lead managers of small-profit firms to spend less than proportionally in the current period when activities are increasing, and to cut down costs more than proportionally in the current period, when activities are decreasing. This alternative explanation would also yield symmetric behavior for small-profit firms for reasons unrelated to incentives to beat the zero earnings benchmark in the current year. To address this concern, we estimate the extended model and split sample regressions including the average sales growth of the three subsequent years. Untabulated findings indicate that inferences are largely unchanged for both small-profit and large-profit observations. In particular, large-profit observations exhibit cost asymmetry for labor costs ($\beta_1 = 0.60$, $t = 9.76$; $\beta_2 = -0.20$, $t = -4.93$), number of employees ($\beta_1 = 0.42$, $t = 10.54$; $\beta_2 = -0.32$, $t = -4.52$), blue- and white-collar workers ($\beta_1 = 0.45$, $t = 6.91$; $\beta_2 = -0.28$, $t = -2.26$ for blue-collar workers; $\beta_1 = 0.40$, $t = 9.06$; $\beta_2 = -0.34$, $t = -4.13$ for white-collar workers), and symmetric behavior for the number of hours per employee ($\beta_1 = 0.21$, $t = 5.42$; $\beta_2 = 0.02$, $t = 0.24$). Small-profit observations exhibit asymmetric behavior in the opposite direction for labor costs ($\beta_1 = 0.26$, $t = 4.53$; $\beta_2 = 0.33$, $t = 2.18$), symmetric behavior for the number of employees ($\beta_1 = 0.21$, $t = 3.78$; $\beta_2 = 0.28$, $t = 1.50$), no reaction to activity changes for the number of hours per employee ($\beta_1 = 0.04$, $t = 1.42$; $\beta_2 = 0.16$, $t = 1.45$) and white-collar workers ($\beta_1 = 0.10$, $t = 1.22$; $\beta_2 = 0.20$, $t = 1.10$), and asymmetric behavior in the opposite direction for the blue-collar workers ($\beta_1 = 0.16$, $t = 1.50$; $\beta_2 = 1.02$, $t = 1.71$).

In contrast, the findings for small-loss firms differ markedly from those reported in Table 7. In particular, small-loss observations exhibit symmetric labor costs once future sales growth is included as a control ($\beta_1 = 0.45$, $t = 3.20$; $\beta_2 = -0.16$, $t = -0.65$). Moreover, the number of white-collar workers is no longer increasing following an activity decrease ($\beta_1 = 0.29$, $t = 2.31$; $\beta_2 = -0.31$, $t = -1.14$). Thus, it appears that failure to control for future growth is responsible for the mixed result for small-loss firms in Table 7.[15]

V. CONCLUSION

This study investigates whether and how incentives to meet or beat the zero earnings benchmark influences labor cost behavior in a sample of private Belgian firms. Our findings show that firms with incentives to meet or beat the zero earnings benchmark limit the increase in labor costs following an activity increase and are more willing to cut labor costs following an activity decrease, which results in symmetric labor cost behavior. Firms that do not face significant pressure from the earnings benchmark exhibit asymmetric labor cost behavior, which is consistent with prior research on SG&A expenditures of publicly traded U.S. firms.

---

[15] Similar to small-profit observations, after controlling for future sales growth, small-loss observations exhibit symmetric behavior for the number of employees ($\beta_1 = 0.24$, $t = 2.59$; $\beta_2 = -0.03$, $t = -0.18$), the number of hours per employee ($\beta_1 = 0.23$, $t = 2.86$; $\beta_2 = -0.31$, $t = -0.89$), and the number of blue-collar workers ($\beta_1 = 0.43$, $t = 2.49$; $\beta_2 = -0.19$, $t = -0.60$).

See Table 2 for variable definitions.

Examination of the underlying managerial decisions shows that managers of firms that report a healthy profit react to activity changes by changing the number of hours that employees work because such an approach limits the damage to their reputation within the firm and in the labor market. Managers of firms that meet or beat the zero earnings benchmark, on the other hand, adjust to activity changes by firing employees, which results in immediate cost reductions. Finally, managers of small-profit firms are more likely to terminate employees who are least costly to fire. Whether managing labor costs in order to meet or beat the zero earnings benchmark harms future firm performance is beyond the scope of this paper, but this question can serve as an interesting topic for follow-up work.

This study extends contemporaneous accounting literature in two ways. First, we present evidence that variations in cost behavior are driven by managerial incentives. Examining the influence of managerial incentives on cost behavior in private firms permits us to focus on managerial incentives in a setting in which agency costs are likely to play a minimal role. Second, we extend recent work in accounting by documenting real managerial decisions with respect to employees. Our findings show that accounting benchmarks influence managerial decision-making with respect to employees and provide potential insights to labor market policy makers.

By design, our focus on labor cost behavior in private Belgian firms limits the generalizability of our results to other types of costs and other institutional settings. However, the primary aim of this paper was to test whether managerial incentives influence cost behavior and this requires a specific institutional setting. Future research may test whether our findings replicate in other institutional settings with other types of incentives and other costs. Furthermore, employee decisions that managers can make to influence their cost level are not limited to hiring and firing decisions and increasing or decreasing the number of hours per employee. We leave to future research the way in which managers use other tools, such as bonus determination and promotion decisions, to influence labor costs.

Rules-Based Accounting Standards and Litigation

Dain C. Donelson
John M. McInnis
The University of Texas at Austin

Richard D. Mergenthaler
The University of Iowa

ABSTRACT: Some claim that rules-based accounting standards shield firms from litigation, while others argue that violations of detailed rules give plaintiffs a "roadmap" to successful litigation. We inform this debate by investigating whether rules-based standards are associated with the incidence and outcome of securities class action litigation. Overall, our results suggest that rules-based standards are associated with a lower incidence of litigation but are not associated with litigation outcomes. These results are of interest in the debate regarding the switch from a more rules-based U.S. GAAP to a more principles-based IFRS.

Keywords: *securities litigation; safe harbor; rules-based standards; principles-based standards.*

JEL Classifications: *K22, K41, M41.*

I. INTRODUCTION

Many practitioners and members of the popular press decry the rules-based nature of U.S. GAAP and propose the adoption of standards that are more principles-based (see, e.g., DiPiazza et al. 2006). The Securities and Exchange Commission (SEC 2010) is considering just such a shift to the more principles-based International Financial Reporting Standards (IFRS). One concern with such proposals is that a move to principles-based standards

will increase firms' exposure to litigation (Schipper 2003). The SEC (2003), however, predicts a decline in litigation if principles-based standards are implemented. Despite the important policy implications, current arguments regarding rules-based standards and litigation rest on rhetoric and there is no clear consensus on their relation to litigation. Schipper (2003, 68) summarizes the need for empirical evidence on this issue, stating that "there is no systematic evidence on the question of whether detailed accounting guidance has any effect on either the incidence or cost of litigation." This study provides such evidence.

In order to understand the role of rules-based standards in accounting-related litigation, it is critical to understand certain aspects of the U.S. securities litigation system. First, securities class actions almost never proceed to trial. As a result, cases that survive the defendant firm's motion to dismiss are almost always settled out of court. This makes the motion to dismiss the pivotal issue in a securities class action suit. To avoid dismissal, plaintiffs must persuasively argue the firm *intentionally* misstated its financial statements, leading to an inflated stock price. Second, plaintiffs are not allowed access to company records through discovery until after they withstand the motion to dismiss, so allegations must draw on publicly available information unless the plaintiff obtains inside information from a whistleblower. Third, because a restatement establishes the misstatement element, intent is usually the only contested question in cases involving restatements. Thus, restatements increase the probability of both a lawsuit filing and a settlement (see Johnson et al. 2007). On the other hand, if firms do not issue restatements, then plaintiffs must convincingly allege both a misstatement and intent.

Against this backdrop, the precise effects of rules-based standards on the threat of litigation are unclear. We distill arguments relating rules-based standards to litigation into two competing theories. The first theory, which we label the "protection" theory, incorporates all arguments that make firms less likely to be sued or less likely to lose conditional on being sued. This theory thus predicts that rules-based standards shield firms from litigation. The competing view is the "roadmap" theory, which includes all arguments that make plaintiffs more likely to file a suit or prevail in a suit conditional on its filing. This theory contends that the specificity of rules-based standards provides plaintiffs with a clear path to successful litigation.

The "protection" theory is based on two arguments. First, when firms do not publicly admit to a misstatement, they can assert that they followed the detailed guidance of rules-based standards. Thus, in cases not involving a restatement, rules provide a "safe harbor" that protects firms from litigation. Principles-based standards, by way of contrast, do not afford such protection, leaving firms open to *ex post* claims that they did not exercise reasonable judgment when preparing financial statements. Second, in cases involving an admitted misstatement, the complex nature of rules-based standards offers an "innocent misstatement" defense that deters litigation. This argument stems from the belief that characteristics of rules-based standards (including volumes of implementation guidance, exceptions, and high levels of detail) make standards complex. Managers violating rules-based standards can argue that the misstatement was an innocent mistake caused by the complexities of GAAP, rather than an intentional violation.

The competing "roadmap" theory only applies to instances in which an identifiable misstatement occurred, as evidenced by a restatement. This theory argues that the detail and objectivity of rules-based standards help to establish intent, as plaintiffs can argue that it is implausible that executives would unintentionally violate the clear guidance provided by a rules-based standard. In essence, this theory is the converse of the innocent misstatement defense discussed above and argues that rules-based standards increase the threat of litigation.

The first challenge in testing these theories involves measuring whether standards are rules-based or principles-based. We identify the key characteristics of rules-based standards espoused by academics, practitioners, and regulators. While some believe that "rules-based" simply refers to bright-line thresholds, such a definition is incomplete. Rules-based accounting standards are highly detailed, contain scope exceptions, and require a significant amount of implementation guidance (e.g., FASB 2002; Nelson 2003; Schipper 2003; SEC 2003; DiPiazza et al. 2006). Despite the perception that U.S. GAAP is rules-based, there is considerable variation in the extent to which U.S. accounting standards exhibit these characteristics (e.g., Cunningham 2007). We exploit these within-GAAP differences and use the Rules-Based Continuum (RBC) score from Mergenthaler (2010) to measure the extent to which individual accounting standards contain: (1) bright-line thresholds, (2) scope and legacy exceptions, (3) large volumes of implementation guidance, and (4) a high level of detail. Higher RBC scores represent standards with more of these rules-based characteristics.

We begin by validating the RBC measure. Across a variety of tests, we find evidence suggesting RBC is a valid proxy that measures whether standards are rules-based. For instance, consistent with common perceptions, our findings suggest that U.S. GAAP is more rules-based than IFRS. In addition, the RBC measure produces high scores for standards the SEC (2003) classified as rules-based in its 2003 report, thus confirming the RBC measure lines up well with the SEC's view of what constitutes a rules-based standard.

Next, we use lawsuits citing specific accounting standards from 1996–2005 to test the protection and roadmap theories. We examine lawsuits in which the defendant firm does not admit to a prior accounting misstatement ("non-restatement cases"), as well as lawsuits where the firm does admit to such a misstatement ("restatement cases"). As discussed above, the protection theory relates to both non-restatement and restatement cases, while the roadmap theory relates only to cases involving accounting restatements.

Non-restatement cases involve the announcement of bad news, which leads to a material stock price drop. Plaintiffs typically argue the financial statements violated GAAP and did not reflect the true economic state of the firm prior to this news revelation. If the protection theory is correct, then we expect plaintiffs to allege relatively principles-based violations in these cases, as plaintiffs will not have the objective evidence provided by a restatement to demonstrate that specific rules-based standards have been violated. Thus, this theory posits that rules-based standards provide a safe harbor from litigation. To test this conjecture, we use each firm as its own control and compare the RBC score of the alleged violations to that of the accounting standards important to the firm—those contained in its Summary of Significant Accounting Policies 10-K disclosure. Consistent with the safe harbor arguments of the protection theory, we find the RBC score of allegedly violated standards in filed lawsuits is significantly lower (i.e., more principles-based) than the RBC score of standards important to the firm. Thus, absent an admitted accounting violation, plaintiffs tend to target principles-based areas of GAAP.

We next examine restatement cases. The protection theory predicts that admitted violations of rules-based standards should be associated with a lower threat of litigation because rules-based standards provide defendants with an innocent misstatement defense. In contrast, the roadmap theory predicts that violations of clear, specific rules-based standards are more likely to be perceived as intentional, which will provide plaintiffs with stronger cases and thereby increase the threat of litigation. To test these theories, we compare our lawsuit sample against a control sample of admitted accounting violations that could have plausibly resulted in a lawsuit, but did not. Specifically, the control sample includes restatements that resulted in a significant decline in market value without associated litigation. We find that violations of rules-based standards are less likely to result in a lawsuit filing, which is consistent with the protection theory. We also examine whether rules-based standards affect case outcomes. Again, the protection and roadmap theories produce competing predictions. We find no evidence that rules-based standards are related to case outcomes. Overall, we find support for the protection theory with respect to litigation incidence but not case outcomes. We find no support for the roadmap theory with respect to litigation incidence or outcomes.

This study makes two contributions. Most importantly, we provide the first archival evidence on the relation between rules-based accounting standards and litigation. Despite important public policy implications, there is a dearth of research in this area. Our evidence is particularly relevant to policy debates because we utilize a comprehensive database of securities class action lawsuits. Our sample comprises the universe of GAAP-related lawsuits that cite accounting standards among economically significant firms from 1996–2005. In addition, we distill arguments relating accounting standards to litigation into a simple framework involving two competing theories. This framework can be used to guide future policy debates and foster additional academic research in this area.

Section II discusses rules-based standards, prior literature, and features of the U.S. litigation environment. Section III discusses the relevant theories in more detail and develops testable hypotheses. Section IV contains our research design, empirical results, and robustness checks. Section V discusses limitations of our study. Section VI concludes and discusses the policy implications of our findings.

II. LITERATURE REVIEW AND INSTITUTIONAL BACKGROUND

Characteristics of Rules-Based Accounting Standards

Despite significant recent focus on rules-based and principles-based accounting standards, "The exact meaning of this distinction is not well defined and is often unclear" (Hail et al. 2010, 376). There is agreement that rules-based standards often involve bright-line thresholds (e.g., Kadous and Mercer 2012). However, a review of commentary by academics and regulators makes it clear that the characteristics of rules-based standards involve more than bright-line thresholds. These characteristics include scope and legacy exceptions, a high level of detail, and extensive implementation guidance (FASB 2002; Nelson 2003; Schipper 2003; SEC 2003).[1] The SEC (2003, 23), for example, indicates that "the primary characteristics of rules-based standards are the existence of exceptions and bright-lines which lead to very detailed implementation guidance."

The SEC (2003) suggests these characteristics make standards more precise and lower the amount of professional judgment required in application. For example, scope and legacy exceptions provide a lengthy list of transactions to which a standard does not apply, making it clearer whether the standard applies to a particular transaction. Increased detail and implementation guidance similarly limit the amount of professional judgment required, while bright-line thresholds provide objective guidance regarding application of the standard. Nelson (2003) notes that the presence of these characteristics makes a standard both more specific and complex, and thus more rules-based.

Many standards begin with a simple principle, but ultimately begin to take on rules-based characteristics. As Schipper (2003, 67) states:

> Once a standard lays out a financial reporting principle, the only way to permit deviations from that principle is to include in the standard a rule or rules that provide for some combination of excluded items (scope exceptions) or items that receive special treatment (legacy exceptions). These rules add to the length and complexity of the standard, and lead to requests for explanations of the breadth of the exceptions.

Because the nature of rules-based standards is multifaceted, we use all of the characteristics described above (bright-line thresholds, scope and legacy exceptions, a high level of detail, and implementation guidance) in our empirical analysis when measuring the extent to which standards are rules-based.

---

[1] Scope and legacy exceptions are exceptions to standards that permit alternative treatments for a defined set of transactions or for a specific industry (Schipper 2003).

Prior Research

Most studies related to rules-based versus principles-based accounting standards investigate whether rules-based standards affect financial reporting decisions.[2] There is significantly less work addressing legal or regulatory enforcement with respect to GAAP violations. Kadous and Mercer (2012) utilize an experiment to investigate the effect of bright-line thresholds on juror decisions in auditor negligence cases.[3] In another recent study, Mergenthaler (2010) finds that the SEC is less likely to penalize a rules-based GAAP violation.

However, no study examines the effect of rules-based standards in the securities litigation context. Regulatory enforcement efforts and auditor negligence cases are not a good proxy for the private enforcement arena of securities litigation due to differing incentives (see Coffee 2006) and institutional details. The SEC is a regulatory agency whose enforcement actions are undertaken to shape financial reporting policy and punish companies for not complying with securities laws (Cox and Thomas 2003). Class action plaintiffs are focused on the potential recoverable settlement amount. In addition, auditor negligence cases have a much lower intent threshold than securities class actions, where fraud must be alleged. Thus, direct evidence on the effect of rules-based standards on the threat of litigation is needed in the securities class action context. As we discuss below, the securities class action litigation environment in the U.S. is unique, and key procedural hurdles must be met for plaintiffs to bring a successful suit.

Securities Litigation Background

The securities class action litigation environment is now largely defined by the Private Securities Litigation Reform Act of 1995 (PSLRA), which was passed to limit frivolous securities litigation. Prior to the passage of the PSLRA, securities class action complaints were often filed whenever a significant stock price decline occurred, regardless of the presence of actual fraud. Complaints were often of low quality and consisted largely of boilerplate allegations (Casey 2008). The PSLRA limits such practice, requiring that complaints allege facts that yield a "strong inference that the defendant acted with the required [fraudulent] state of mind" (15 U.S.C. section 78u-4(b)(2)).[4] The PSLRA also prevents discovery until after a motion to dismiss is decided, making the motion to dismiss the key procedural hurdle.[5]

To survive a motion to dismiss, a complaint must allege facts sufficient to satisfy each element of Rule 10b-5, including "(1) a misstatement or omission of (2) a material fact (3) made with intent (4) that the plaintiff justifiably relied on (5) causing injury in connection with the purchase or sale of securities" (Skinner 1994).[6] Based on the elements of Rule 10b-5, accounting-related securities class action lawsuits follow a reasonably predictable pattern. First, to satisfy element (1), a firm either admits to a misstatement by restating its prior financial statements ("restatement cases"), or shareholders infer a misstatement or omission of prior financial statements ("non-restatement cases"). Second, the revelation or alleged discovery of the misstatement is accompanied by a large stock price decline, satisfying elements (2) (materiality) and (5) (causation). Element (4) is generally presumed under the fraud on the market theory (see Francis et al. 1994). Thus, the key element in most accounting-based securities litigation is element (3), fraudulent intent (see Pritchard and Sale 2005). To establish intent, the plaintiff must be able to allege facts that indicate that the defendant firm's managers acted with scienter. In the law, acting with scienter means that the defendant's attempt to deceive or defraud was intentional or so reckless that the act "reflects some degree of intentional or conscious misconduct" (*In re Silicon Graphics, Inc. Securities Litigation*, 183 F.3d 970, 977 (9th Cir. 1999)). If the plaintiffs' complaint alleges scienter with sufficient factual detail and is not dismissed, then securities class action lawsuits almost always settle rather than go to trial.

---

[2] Nelson et al. (2002) find that executives manage earnings by structuring transactions when standards are "precise," and that executives manage earnings in an "unstructured" manner when standards are "imprecise." Cuccia et al. (1995) provide evidence that executives use judgment to defend aggressive tax behavior when standards are vague, and that they evaluate the evidence in a manner consistent with the desired outcome when standards are strict. Mergenthaler (2010) finds that the magnitude of earnings management is larger when a rules-based standard is violated. Finally, Jamal and Tan (2010) find that while managers' decisions may differ based on the type of accounting standard, their reporting choices are affected by auditor type (principles-oriented, rules-oriented, or client-oriented).

[3] Kadous and Mercer (2012) find that bright-lines shield auditors from litigation when the client reporting decision is both conservative and deviates from the industry norm. However, they find that merely complying with the industry norm renders the bright-line threshold unimportant in such cases. When the client reporting decision is aggressive, however, bright-lines increase liability of auditors, regardless of compliance with industry norms.

[4] The Supreme Court interpreted the "strong inference" requirement to mean that an inference of fraud "must be more than merely plausible or reasonable—it must be cogent and at least as compelling as any opposing inference of non-fraudulent intent" (*Tellabs, Inc. v. Makor Issues & Rights, Ltd.*, 551 U.S. 308 (2007)).

[5] Preventing discovery greatly reduces the cost of non-meritorious suits. However, if a motion to dismiss fails, then corporations are subject to discovery, requiring high-level officials to submit to depositions and document production. Thus, even if a company believes it would prevail at trial, it is cost-efficient to settle to avoid litigation costs and the large potential damages associated with losing a class action case (e.g., Pritchard and Sale 2005).

III. HYPOTHESES DEVELOPMENT

We review the academic literature, popular press articles, and U.S. case law to distill arguments on the relation between rules-based accounting standards and litigation into two competing theories. Figure 1 outlines the two theories (described in Row A). We label the first the "protection" theory, which incorporates all arguments that make the firm less likely to be sued or less likely to lose if they are sued. In other words, the protection theory contends that rules-based standards decrease the threat of litigation. We label the second the "roadmap" theory, which includes all arguments that make plaintiffs more likely to file a suit or prevail in a suit conditional on its filing. In other words, this theory contends that rules-based standards increase the threat of litigation.

Figure 1 next provides a discussion of the elements of each theory (described in Row B), and relates these elements to observable events—whether a restatement has been issued by the firm (described in Row C). Linking the theories to these observable events is important because the protection theory offers predictions in both non-restatement and restatement cases (detailed on the left side of Figure 1), while the roadmap theory only deals with detected misstatements and thus only offers a prediction for restatement cases (detailed on the right side of Figure 1). Therefore, we organize our hypotheses and tests around whether a restatement is present. We begin with non-restatement cases for which our only hypothesis comes from the protection theory, due to the inapplicability of the roadmap theory in such cases.

Non-Restatement Cases

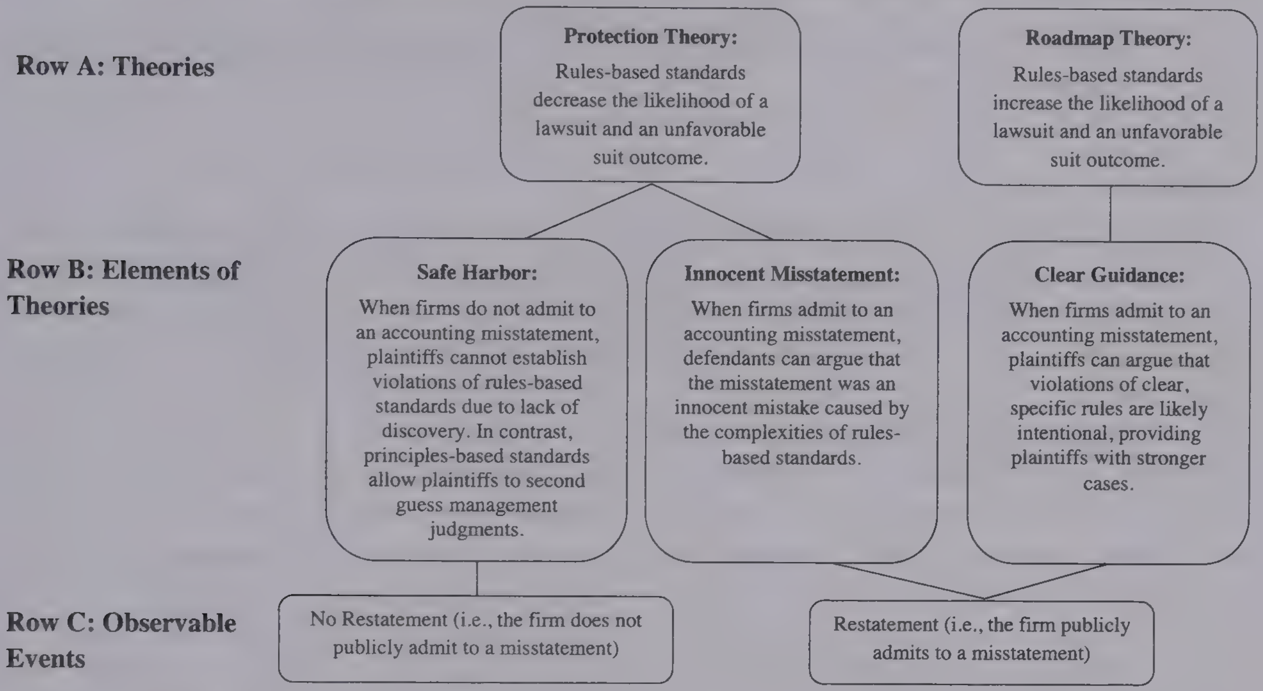
In cases not involving a restatement, plaintiffs must argue that defendants misstated their financial statements and that the misstatement was intentional. These cases typically arise following the announcement of bad news that results in a significant stock price drop. Plaintiffs usually allege that a firm's financial statements were misstated in violation of GAAP and did not accurately portray the underlying economic state of the firm prior to the stock price drop.[7] Plaintiffs must be

---

[6] Firms may also be liable under Section 11 of the 1933 Securities Act, but only in connection with the public offering of securities. The elements of a Section 11 violation are similar to Rule 10b-5, except that the intent standard is lower.

[7] In these cases, defendants do not admit to a misstatement and do not restate their financial statements, even if the case is ultimately settled. Settlement in these cases is generally undertaken to avoid the cost of a trial (and a potentially sizable jury verdict) once the court denies a motion to dismiss. The defendant generally does not admit wrongdoing, even in the settlement agreement (Alexander 1991).

FIGURE 1
Summary of Theories Relating Rules-Based Accounting Standards and Litigation



Row A: Theories
Protection Theory:
Rules-based standards decrease the likelihood of a lawsuit and an unfavorable suit outcome.
Roadmap Theory:
Rules-based standards increase the likelihood of a lawsuit and an unfavorable suit outcome.
Row B: Elements of Theories
Safe Harbor:
When firms do not admit to an accounting misstatement, plaintiffs cannot establish violations of rules-based standards due to lack of discovery. In contrast, principles-based standards allow plaintiffs to second guess management judgments.
Innocent Misstatement:
When firms admit to an accounting misstatement, defendants can argue that the misstatement was an innocent mistake caused by the complexities of rules-based standards.
Clear Guidance:
When firms admit to an accounting misstatement, plaintiffs can argue that violations of clear, specific rules are likely intentional, providing plaintiffs with stronger cases.
Row C: Observable Events
No Restatement (i.e., the firm does not publicly admit to a misstatement)
Restatement (i.e., the firm publicly admits to a misstatement)

This figure summarizes the theories that suggest a relation between rules-based standards and litigation. The protection theory applies regardless of whether the firm publicly admits to a misstatement. The roadmap theory only applies when firms publicly admit to a misstatement. Absent such an admission, plaintiffs cannot determine whether firms followed the rules because discovery is not permissible until after the dismissal decision. Thus, without a restatement, plaintiffs generally cannot establish violations of specific rules as required by the roadmap theory.

able to "plead" (present in the complaint) facts that support these elements without access to company records via discovery. Thus, plaintiffs rely on publicly available information to make their initial case, absent a whistleblower.

The arguments for the protection theory as they apply in non-restatement cases are summarized in Figure 1, Row B in the "Safe Harbor" box. Specifically, the protection theory argues that rules-based accounting standards decrease the threat of litigation in non-restatement cases. Under this argument, the detailed guidance provided by rules-based standards provides firms with "safe harbor" protection from litigation when firms follow the rules (Schipper 2003; SEC 2003). Reinforcing this aspect of the protection theory, it is also difficult for potential plaintiffs to allege a specific violation of a rules-based standard due to the lack of discovery. Without discovery, plaintiffs are unable to observe sufficient detail about a firm's transactions to know whether a rules-based accounting standard was violated. For example, it would be difficult to determine whether a bright-line was crossed, the requirements of an exception were met, or whether the transaction fit into a particular area of implementation guidance without either specific records of transactions or testimony from individuals involved in the transaction.

On the other hand, principles-based standards are subject to more judgment and have less objective criteria compared to rules-based standards, so plaintiffs can more persuasively allege that their application was improper and "second guess" accounting decisions after the fact. Even if a firm attempts to follow a principles-based standard, its decision may still be questioned by plaintiffs due to the discretion involved.

Overall, in cases not involving a restatement, the protection theory predicts that rules-based standards will tend to shield firms from litigation and plaintiffs will thus tend to allege violations of principles-based standards. We state our first hypothesis in the alternative:

> **H1:** Plaintiffs are less likely to allege violations of rules-based accounting standards in non-restatement cases.

Restatement Cases

We next consider restatement cases for which the protection and roadmap theories offer competing predictions. In restatement cases, defendant firms admit to an accounting misstatement via a restatement before or soon after the filing of a lawsuit. Thus, the misstatement element is not disputed and the safe harbor protection that accompanies compliance with rules-based standards is inapplicable.

The protection theory suggests that rules-based standards shield firms from litigation, even after a restatement. Rules-based standards include exceptions, high levels of detail, and large amounts of implementation guidance, making such standards more complex and difficult to apply than principles-based standards. Managers can therefore utilize the complex nature of rules-based standards to argue that violations of rules-based standards were "innocent misstatements." Both standard-setters and courts agree that complex standards are more difficult to apply and can lead to errors. For instance, the former Chairman of the IASB, David Tweedie (2007, 5), stated that rules-based standards "frequently baffle many accountants so much so that few audit partners can complete an audit without relying on the advice of experts within the firm." In the Microstrategy case (*In re Microstrategy, Inc. Securities Litigation*, 115 F. Supp. 620, 652 (E.D. Va. 2000)), the court held that the more complex the accounting standard, the lower the inference of fraudulent intent. Furthermore, courts generally assume misstatements are innocent errors, absent convincing evidence of intent (scienter) and "the mere publication of inaccurate accounting figures, or a failure to follow GAAP, without more, does not establish scienter" (*Dsam Global Value Fund v. Altris Software, Inc.*, 299 F.3d 385 (9th Cir. 2002)). These arguments are summarized in Figure 1, Row B, in the "Innocent Misstatement" box.

Proponents of the "roadmap" theory offer an alternative view, contending that rules-based standards provide plaintiffs with a guide to successful litigation. The idea behind the roadmap theory is that violations of rules-based standards help demonstrate intent, as plaintiffs can argue that it is implausible that executives would unintentionally violate a specific rule that provides clear guidance. For example, Leone (2009) cites a veteran securities litigator who notes that "in a case based on a principle, it's 'really hard' to prove that executives or directors acted in bad faith." The roadmap view also predicts that the objectivity and specificity of rules-based standards make it easier to identify accounting misstatements, triggering restatements. Since restatements tend to increase the threat of a lawsuit and lead to more favorable outcomes for plaintiffs (Johnson et al. 2007), the roadmap theory predicts that rules-based (principles-based) standards increase (decrease) litigation risk. For example, Bogoslaw (2008) states that "the big accounting firms that are drawn to [a more principles-based] IFRS believe they'll get sued less since it will be harder to point to their mistakes."[8] These arguments are summarized on the right side of Figure 1, Row B, in the "Clear Guidance" box. Overall, the roadmap theory predicts that violations of rules-based standards will increase the threat of litigation, while the protection theory predicts the opposite. Although both arguments seem plausible, the "innocent misstatement" defense of the protection theory is more strongly supported by U.S. case law. We therefore state our second hypothesis as follows:

---

[8] Under this portion of the roadmap theory, it is possible that principles-based standards may shield firms from litigation if violations of these standards are more difficult to detect and, thus, are less likely to result in restatements, but testing this aspect of the roadmap theory is beyond the scope of our study because we are unable to model the restatement decision (i.e., we cannot observe potential misstatements that did not result in a restatement).

> **H2:** Violations of rules-based standards are negatively associated with the incidence of litigation in restatement cases.

Although we focus primarily on the lawsuit filing decision, we also examine case outcomes to present a more complete picture of the litigation process. From the discussion above, the roadmap theory predicts that violations of rules-based standards will lead to better outcomes for plaintiffs, including a greater settlement probability in restatement cases. The protection theory again predicts the opposite in restatement cases, as shown in the "Innocent Misstatement" and "Clear Guidance" boxes of Figure 1, Row B. Again, since the "innocent misstatement" defense of the protection theory appears to have more support in case law, we state our third hypothesis as follows:

> **H3:** Violations of rules-based standards are negatively associated with the plaintiffs' outcome in restatement cases.

If plaintiffs' attorneys consider the effect of rules-based standards on case outcomes at the filing stage, then this could lead to no relation between rules-based standards and suit outcomes *among filed cases*. For example, if H2 is true and cases involving rules-based standards have poorer prospects for plaintiffs on average, those cases involving rules-based standards that plaintiffs do choose to file may have relatively high prospects along other dimensions. Thus, among cases actually filed, this selection effect could lead to no relation between rules-based standards and lawsuit outcomes.

IV. EMPIRICAL ANALYSIS

Measurement of Rules-Based Standards

To determine the extent to which a standard is "rules-based," we utilize the Rules-Based Continuum (RBC) score from Mergenthaler (2010) to measure the presence of rules-based characteristics for accounting standards in our sample. Because many accounting standards are based upon broad principles from the FASB conceptual framework, we avoid subjectively classifying standards as being rules-based or principles-based. Instead, we adopt an empirical perspective and focus on the presence or absence of rules-based characteristics identified by prior literature.

The RBC score measures the extent to which standards contain the rules-based characteristics noted in Section II, including (1) bright-line thresholds, (2) scope and legacy exceptions, (3) large volumes of implementation guidance, and (4) a high level of detail. The RBC score increases by 1 for each such characteristic a standard contains.[9] Thus, the value of the RBC score ranges from 0 (a standard contains none of the characteristics, representing a principles-based standard) to 4 (a standard contains all of the characteristics, representing a highly rules-based standard).[10]

---

[9] The number of FASB "interpretive pronouncements" is the proxy for the amount of implementation guidance. Standards ranked in the upper decile of interpretive pronouncements are classified as having large volumes of implementation guidance. The number of words in a standard measures detail, with standards in the upper word count decile classified as having a high level of detail. We also examine whether our results hold when we change our definition of large volumes of implementation guidance and detail to be the upper quartile of the distribution and find that our results are robust to this alternative way of defining these characteristics.

RBC Validation

We validate the RBC score in three ways to ensure that we are capturing the underlying construct of rules-based accounting standards. First, we demonstrate that the four dimensions of *RBC* are all positively correlated. Panel A of Table 1 provides the correlations between the four dimensions that comprise the RBC score in our sample. Standards with bright-line thresholds, for example, tend to have more implementation guidance ($\rho = 0.55$). An untabulated factor analysis reveals only one significant factor in the data, consistent with the notion that the four elements of the RBC score proxy for a common construct. Thus, we aggregate the four characteristics into one measure.

Second, Panel B of Table 1 outlines the RBC score for select standards the SEC (2003) classified as "principles-based" or "rules-based" and demonstrates a consistent overall relation between the RBC score and the SEC's perception of "rules-based" accounting standards. In fact, the RBC score for almost all of the standards the SEC classifies as "principles-based" ("rules-based") have a low (high) RBC score. For instance, ARB 43-4 (inventory pricing), a standard the SEC referred to as "principles-based," has an RBC score of 0, indicating that ARB 43-4 does not contain any of the aforementioned rules-based characteristics. On the other hand, SFAS 13 (leases), a "rules-based" standard per the SEC, has a score of 4, indicating that it contains all of the rules-based characteristics and is therefore more rules-based. SFAS 133 (derivatives) has an RBC score of 3, also consistent with relatively high rules-based content and the SEC classification.

There are three standards in which the SEC's classification of a standard as "principles-based" does not match well with the RBC score: business combinations (SFAS 141), goodwill (SFAS 142), and long-lived asset impairment (SFAS 144). While none of these standards contain bright-line thresholds, they each contain scope exceptions and a high level of implementation guidance. In addition, each standard is very detailed, with total lengths of 19,298 words (SFAS 141), 18,824 words (SFAS 142), and 21,259 words (SFAS 144). These standards have fairly high RBC scores as they exhibit all rules-based characteristics other than bright-line thresholds. Thus, despite the inconsistency with the SEC treatment, the *RBC* classification of these standards as relatively rules-based seems reasonable.[11]

Third, for each U.S. standard examined by the SEC (2003), we compute the RBC score for the corresponding IFRS standard. After tabulating the RBC score, we compare the RBC score of each IFRS standard to that of the corresponding U.S. GAAP standard. This comparison is meaningful because IFRS is commonly perceived to be less rules-based than U.S. GAAP. Thus, if the RBC score correctly measures whether a standard is rules-based, then RBC scores should be higher for U.S. GAAP than for IFRS. In almost all cases, the RBC score for the IFRS standard is less than or equal to the RBC score for the corresponding U.S. GAAP standard. An untabulated test of differences in the median (mean) RBC score reveals that the median (mean) RBC score of the IFRS standards presented is significantly lower (z-statistic $= -2.29$, one-sided p-value $= 0.01$; t-statistic $= -1.95$, one-sided p-value $= 0.03$) than the RBC score of the corresponding U.S. GAAP standards. We view the higher RBC score of U.S. GAAP relative to IFRS as a particularly interesting finding because the underlying transactions are held constant across accounting regimes. Thus, the RBC

---

[10] *RBC* is calculated each year for each standard because standards change over time as detail, exceptions, and implementation guidance are added.

[11] Schipper (2003) discusses SFAS 141 and 142 as being based on principles, but suggests that additional guidance provided by the FASB makes these standards more rules-based.

TABLE 1

Rules-Based Continuum Construct Validity

Panel A: Pearson Correlations among Rules-Based Characteristics

	Detail	Implementation Guidance	Exceptions
Implementation Guidance	0.62 (< 0.0001)		
Exceptions	0.25 (< 0.0001)	0.65 (< 0.0001)	
Bright-Line Thresholds	0.19 (< 0.0001)	0.55 (< 0.0001)	0.38 (< 0.0001)

Panel A displays Pearson correlations between the individual characteristics of rules-based standards.

Panel B: Comparison of Select IFRS and U.S. GAAP Standards

Description	IFRS Standard	IFRS *RBC*	U.S. Standard	U.S. *RBC*	SEC Classification
Recognition of Financial Assets/Liabilities	IAS 39	3	SFAS 140	4	Rules-Based
Other Post-Retirement Benefits	IAS 19	2	SFAS 106	4	Rules-Based

Panel B presents data on the median RBC score for standards the SEC classified as "rules-based" or "principles-based" and presents the RBC score of the corresponding IFRS standards.

RBC measures whether a standard contains bright-line thresholds, scope and legacy exceptions, large volumes of implementation guidance, and a high level of detail. *RBC* increases by 1 when a standard contains any one of the above-mentioned criteria. *RBC* is calculated each year for each standard because standards change over time as detail, exceptions, and implementation guidance are added.

score captures differences in the characteristics of accounting standards independent of the transactions underlying the standards.

Collectively, results from the correlations between the components of *RBC*, the factor analysis, the comparison to standards classified by the SEC, and the comparison to IFRS validate the RBC score and suggest that it is a reasonable measure of whether a standard contains rules-based characteristics.

Sample

We select all resolved securities class action lawsuits filed from 1996 to 2005 alleging GAAP violations from the Securities Class Action Services (SCAS) database from RiskMetrics Group. We exclude suits based purely on disclosure theories outside financial reporting. We end the sample in 2005 because we require settlement outcomes in later tests, and cases generally take several years to resolve. Starting the sample in 1996 ensures that all suits occur within a similar legal framework under the PSLRA.

We examine lawsuits involving common stockholders and require defendant firms to have coverage in I/B/E/S and CRSP. Requiring analyst coverage aids in ensuring reasonably efficient incorporation of information into stock prices (Piotroski and Roulstone 2004). Requiring CRSP coverage excludes thinly traded OTC stocks. Together, these restrictions ensure that sued firms are of interest to a broad range of investors and are economically significant. We also require firms to have non-missing values for the variables in our empirical tests.

For firms that meet these data requirements, we also screen for an available plaintiff complaint in the Stanford Securities Class Action Clearinghouse. We read each complaint and note the accounting standards allegedly violated, and collect additional variables used in our empirical analysis.[12] This procedure yields 353 cases that cite specific accounting standards, as show in the top box of Figure 2. Figure 2 provides a summary of our samples, including the portion of the lawsuit sample and the designated control sample utilized in each test.

From the 353 total cases that cite accounting standards, 164 do not involve an admitted accounting misstatement by the defendant firm. We identify these non-restatement suits by searching the complaint for the term "restat*" and initially classify cases not containing this term as non-restatement cases. To verify that these suits did not involve a restatement, we further search all 10-K and 10-Q filings for up to one year after the class period end date to verify that the firm did not restate their financial statements prior to the plaintiffs' filing decision. This sample of 164 lawsuits without restatements is located on the bottom left of Figure 2. We use this sample to test H1 by comparing standards cited in the suit to the firm's significant accounting policies (described in more detail below), which applies to the "Safe Harbor" element of rules-based standards as detailed in the "Hypotheses Development" section and in Figure 1, Row B.

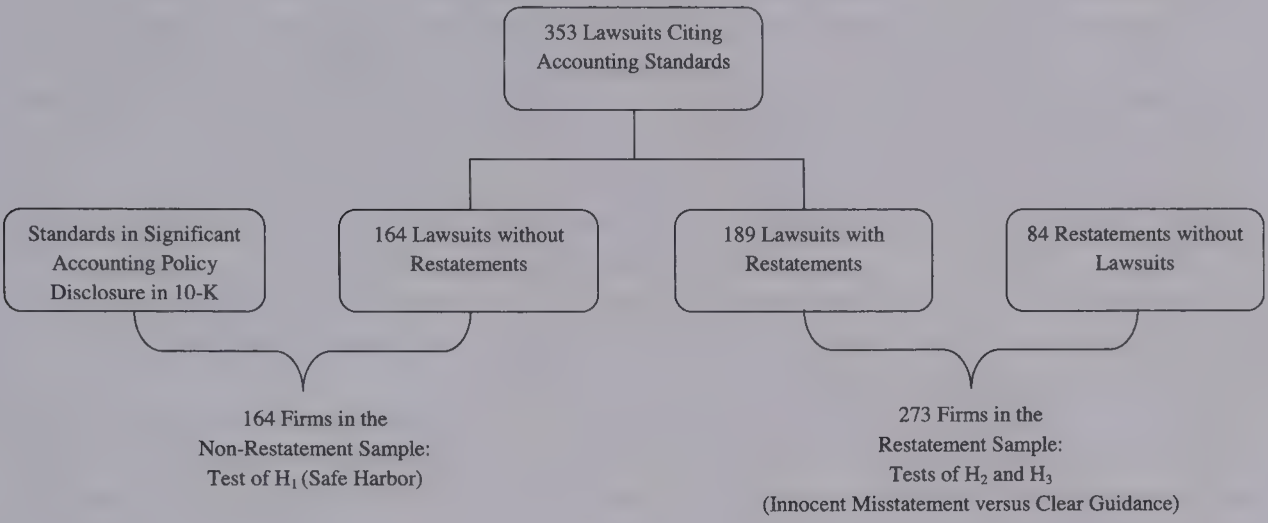
The remaining 189 cases involve an admitted misstatement in the form of a restatement of class period financial statements by the defendant firm. As a control sample, we select all restatements identified by the Government Accountability Office (GAO) from the same time period that did not result in litigation, but whose announcements were accompanied by a decline in market value of equity of at least $50 million, resulting in 84 restatements.[13] We use the $50 million cutoff because

---

[12] To determine if plaintiffs strategically cite certain standards, we selected a random sample of 50 restatement cases. We then compared the violations noted in the complaint to those noted in the restatement. Of the 50 cases we looked at, 48 cite every GAAP violation noted in the restatement. The two remaining cases cited all standards except standards noted as "minor errors" in the restatement. Thus, the plaintiff appears to cite all GAAP violations noted in the restatement filing.

[13] We obtain these restatements from the 1997–2006 GAO sample, which is used in the Hennes et al. (2008) study and is available in machine readable format on Andrew Leone's website (http://sbaleone.bus.miami.edu/).

FIGURE 2
Sample Overview



353 Lawsuits Citing Accounting Standards
Standards in Significant Accounting Policy Disclosure in 10-K
164 Lawsuits without Restatements
189 Lawsuits with Restatements
84 Restatements without Lawsuits
164 Firms in the Non-Restatement Sample: Test of H_1 (Safe Harbor)
273 Firms in the Restatement Sample: Tests of H_2 and H_3 (Innocent Misstatement versus Clear Guidance)

This figure outlines the samples used in our various analyses. We start with 353 lawsuits that cite accounting standards. We then distinguish between lawsuits involving restatements and those not involving restatements. Plaintiffs have different information about the alleged GAAP violation in restatement and non-restatement cases because discovery is not allowed until after the dismissal decision. Thus, in non-restatement cases, plaintiffs must build their cases on publicly available information without direct admission of a misstatement. Our first analysis focuses on lawsuits not involving a restatement. Our sample consists of 164 non-restatement lawsuits, with each sued firm serving as its own control. We compare the standards cited in the lawsuit to those mentioned in the firms' significant accounting policy disclosures. Our second set of tests focus on instances where a restatement is observed. In our sample of lawsuits citing accounting standards, there are 189 lawsuits involving restatements. We then select a sample of "potential lawsuits" involving restatements where the firm restated earnings and the firm's market value dropped $50 million or more around the announcement of the restatement. The 84 restatements in the control sample are obtained from the 1997–2006 GAO sample, which is used in the Hennes et al. (2008) study and is available in machine readable format on Andrew Leone's website (http://sbaleone.bus.miami.edu/). We compare the standards cited in the lawsuits to those disclosed in connection with the non-sued firms' restatements.

potential damages are an important consideration in the filing decision (Coffee 2006; Alexander 1991). We use these 273 restatement observations (189 that triggered lawsuits and 84 that did not, as detailed on the bottom right of Figure 2) to test H2 and H3, which deal with testing the competing "Innocent Misstatement" and "Clear Guidance" aspects of rules-based standards, as detailed in the hypothesis development and in Figure 1, Row B.

Test of H1

To test H1, we search the complaint document to identify each alleged violation and ensure that the firm did not restate earnings. We then read the firm's significant accounting policy disclosure in the firm's 10-K from the alleged violation period to identify the standards that the firm labels "significant." Classifying the significant accounting standards for each firm provides a sample of standards important to the firm that the plaintiff could observe and thus could have alleged the firm violated. We then compare the average RBC score across all of the alleged violations for each lawsuit to the average RBC score across all of the standards contained in the significant accounting policies. Because each sued firm serves as its own control, we conduct our analysis on a univariate basis. A significantly lower RBC score for the alleged violations in lawsuits would indicate that plaintiffs tend to allege more principles-based standards when firms do not admit to a GAAP violation.

Appendix A provides one example of a firm's significant accounting policy disclosure and documents how we classified this disclosure to identify the firm's significant accounting standards. In this example of Policy Management Systems Corp., we list the identified standards and their RBC measures immediately before the paragraphs discussing each significant accounting policy.

Panel A of Table 2 provides descriptive statistics for the non-restatement cases. The mean RBC score of the alleged violations is 0.87, suggesting that alleged GAAP violations contain roughly one rules-based characteristic. Consistent with expectations, the disclosure of bad news at the end of the class period elicits an average return of negative 25.08 percent. In untabulated analysis, we find that the most common events triggering these cases include (with the incidence in parentheses): earnings warnings (48.2 percent), earnings announcements revealing poor performance (17.7 percent), announcements of internal or external investigations (11.0 percent), and announcements of bankruptcy/insolvency issues (4.9 percent).[14] Finally, 41 percent of these firms come from high litigation risk industries, as identified by Francis et al. (1994).

Panel B of Table 2 provides the 15 most commonly cited accounting standards in plaintiff complaints along with the 15 most common standards associated with defendants' significant accounting policies. The most commonly cited standards in non-restatement lawsuits include APB 22 (disclosure of accounting policies, $RBC = 0$), SFAS 5 (contingencies, $RBC = 1$), SFAC 5-6 (revenue, $RBC = 1$), SFAS 48 (right of return, $RBC = 1$), and ARB 43-4 (inventory write downs, $RBC = 0$).

The most common standards significant to these defendants include ARB 51 (consolidation, $RBC = 3$), ARB 43-9 (depreciation, $RBC = 0$), SFAC 5-6 (revenue, $RBC = 1$), SFAS 109 (taxes, $RBC = 4$), and SFAS 128 (EPS, $RBC = 3$). A visual comparison of the RBC scores in Panel B suggests that standards allegedly violated in non-restatement cases are less rules-based on average than firms' significant accounting standards.

Panel C of Table 2 provides a test of the differences between the mean (median) RBC score across the two samples. The standards that were allegedly violated according to the plaintiffs' complaints contain fewer rules-based characteristics than the firms' significant accounting standards (t-statistic $= -16.90$ for mean comparison, z-statistic $= -13.00$ for median comparison, both p-values < 0.01). The difference in RBC scores suggests that when selecting from a list of potential violations in non-restatement cases, plaintiffs tend to select standards that are relatively more principles-based.[15] This evidence supports H1 and is consistent with the "safe harbor" aspect of the protection hypothesis, which argues that plaintiffs will avoid rules-based standards and target principles-based standards in litigation because plaintiffs can second-guess managements' judgment more effectively under principles-based standards.

Robustness Tests for H1

One concern with our analysis above is that firms' significant accounting policies may not be an appropriate set of standards to benchmark against standards cited in lawsuit allegations. For example, firms may be unlikely to violate significant accounting policies because these standards receive more audit scrutiny.[16] If so, then comparing the allegedly violated accounting standards to significant accounting policies may not be an appropriate test.

---

[14] Other less common events include announcements for defective products or patent infringement, nonfinancial fraud or enforcement actions, analyst or rating downgrades, and auditor disputes.

[15] To ensure results are not driven by the tendency of plaintiffs to cite revenue standards, which tend to be relatively principles-based, we re-ran this comparison by recalculating *RBC* after dropping all revenue standards cited in the lawsuits and the summary of significant accounting policies. Inferences are similar to those reported above.

[16] We thank an anonymous referee for this suggestion.

Panel A presents descriptive statistics for lawsuits where the firm does not restate earnings from the alleged violation period. Hence, the plaintiff alleges that GAAP was violated, but the firm does not admit to a violation. We label these lawsuits as "non-restatement lawsuits." We obtain lawsuit data from the RiskMetrics Securities Class Action Services database and complaints from the Stanford Securities Class Action Clearinghouse. We obtain the standards mentioned in the firm's significant accounting policies from each firm's 10-K that is filed closest to the lawsuit filing date. Variables are defined in Appendix B.

Panel B: Most Common Accounting Standards

	Non-Restatement Lawsuits			Significant Accounting Policies	
Standard	Description	*RBC*	Standard	Description	*RBC*
APB 10	Revenue Recognition/Taxes	0	ARB 43-4	Inventory Pricing	0
APB 22	Disclosure of Accounting Policies	0	ARB 43-9	PP&E Depreciation and Valuation	0

TABLE 2 (continued)

Non-Restatement Lawsuits			Significant Accounting Policies		
Standard	Description	*RBC*	Standard	Description	*RBC*
SAB 101	Revenue Recognition	2	SFAS 142	Intangible Assets	3
SOP 97-2	Revenue Recognition (Software)	2	SFAS 109	Taxes	4
SFAS 115	Investments in Debt and Equity Securities	3	SFAS 123	Stock Option Compensation	4

Panel B reports the 15 standards most commonly cited in non-restatement cases and these firms' significant accounting policy disclosure. The RBC score of these standards is also presented. The RBC score measures whether a standard contains bright-line thresholds, scope and legacy exceptions, large volumes of implementation guidance, and a high level of detail. *RBC* increases by 1 when a standard contains any one of the above-mentioned criteria. *RBC* is calculated each year for each standard because standards change over time as detail, exceptions, and implementation guidance are added. The RBC score reported is the median RBC score over our sample time period (1996–2006). The table is sorted by RBC score.

Panel C: Differences in Average RBC Scores

	RBC of Alleged Violations		RBC of Significant Accounting Policies		Difference	
n	Mean	Median	Mean	Median	Mean	Median
163	0.80	0.87	1.73	1.73	0.93*** (−16.90)	0.86*** (−13.00)

*, **, *** Indicate significant differences across groups at 0.10, 0.05, and 0.01 levels, respectively (two-tailed).
Panel C presents a test of H1, the protection theory. In Panel C, we test differences in means (medians) across groups and present the t-statistic (z-statistic) below the Difference column. We were unable to obtain a 10-K for one non-restatement lawsuit firm and thus the tests performed in Panel C are performed with a sample of 163 firms.

We conduct two additional tests to address this concern. First, we calculate the proportion of all non-restatement lawsuits that allege a violation of at least one significant accounting policy. We find that this proportion is 75 percent (untabulated). Using a random sample of 50 observations from our restatement lawsuits, we find very similar results with 72 percent of these firms admitting to violating at least one significant accounting policy (untabulated). Overall, it appears fairly common for lawsuits to involve alleged or admitted violations of significant accounting policies.

For our second test, we use a benchmark sample other than significant accounting policies to compare against the *RBC* of non-restatement lawsuit allegations. Specifically, we use the *RBC* of sued and non-sued restatements. Unlike the summary of significant accounting policies, these observations represent standards that firms admit to violating. In untabulated tests, we find that mean and median RBC scores for sued and non-sued restatements are significantly higher than the RBC score of allegations in our non-restatement lawsuit sample. Overall, this evidence suggests that allegations in non-restatement lawsuits are relatively principles-based, regardless of the benchmark used for comparison, consistent with H1 and the "safe harbor" element of the protection theory.

Test of H2

To test H2, concerning the effect of rules-based accounting standards on the filing of lawsuits when a GAAP violation (restatement) occurs, we estimate the following logistic regression:

$$Prob(Sued = 1) = F\Big(\alpha + \beta_1 RBC + \beta'(Controls)\Big). \qquad (1)$$

Sued is a dichotomous variable that is set to 1 if a lawsuit is filed, and is set to 0 otherwise. *F* is the cumulative distribution function of the logistic distribution, and *RBC* is as defined above for the accounting standard that was violated. For restatements not resulting in a lawsuit, we manually review the restatement footnote from the applicable 10-K to identify the accounting standards involved. As multiple standards are usually violated, the average *RBC* of all standards violated is used for both filed suits and non-suits. The coefficient estimate on *RBC*, β_1, provides evidence on H2. A negative β_1 coefficient estimate would suggest that firms violating rules-based standards are less likely to be sued than firms violating principles-based standards, consistent with the "innocent misstatement" aspect of protection theory. A positive β_1 coefficient estimate would suggest the opposite and be consistent with the roadmap theory.

Unlike our test of H1, we are unable to use each firm as its own control to test H2 and must utilize a sample of sued and non-sued firms. To control for differences between sued and non-sued firms, we include firm size, profitability, the presence of a Big 4 or predecessor auditor, stock returns around announcement of the restatement, shareholder damages, insider selling activity, stock issuances, share turnover, stock price volatility, and indicator variables for high litigation risk industries and whether revenue was allegedly misstated.[17] Appendix B defines these control variables that prior research finds to be related to litigation incidence (e.g., Palmrose and Scholz 2004; Francis et al. 1994; Shu 2000).

Descriptive Statistics

Panel A of Table 3 contains descriptive statistics for our sample involving restatements. The first set of columns provides descriptive statistics for restatement firms with a lawsuit, and the second set of columns provides descriptive statistics for restatement firms without a lawsuit. The difference in the mean RBC score between the lawsuit (1.25) and no lawsuit (2.63) samples is stark and significant at the 1 percent level. Restatement firms without lawsuits are larger and more profitable. Not surprisingly, these firms also have less severe announcement returns, smaller damages, fewer revenue restatements, lower share turnover, and less volatile returns.

Panel B of Table 3 tabulates the 15 most commonly violated accounting standards in restatements with lawsuits along with the 15 most commonly violated standards in restatements without lawsuits. The most commonly cited standards in restatements with lawsuits include APB 28 (interim reporting, *RBC* = 0), SFAS 5 (contingencies, *RBC* = 1), SFAC 5-6 (revenue, *RBC* = 1), SFAS 48 (right of return, *RBC* = 1), and SAB 101 (revenue, *RBC* = 2).[18]

The most common standards in restatements without lawsuits include SFAS 109 (taxes, *RBC* = 4), SAB 101 (revenue, *RBC* = 2), SFAC 5-6 (revenue, *RBC* = 1), SFAS 133 (derivatives, *RBC* = 3), SFAS 13 (leases, *RBC* = 4), and SFAS 5 (contingencies, *RBC* =1). Consistent with Panel A, visual comparison of the RBC scores in Panel B suggests that standards violated in restatements with lawsuits are less rules-based on average than standards violated in restatements without lawsuits.

---

[17] We also re-ran our analysis utilizing abnormal (market-adjusted) returns. Our inferences remain unchanged using this alternative specification.

[18] As seen in Tables 2 and 3, plaintiffs commonly allege violations of APB 20 (Correction of Errors) and APB 28 (Interim Financial Reporting). Further review indicates that plaintiffs often allege these violations whenever the firm restates earnings or when the plaintiff alleges a GAAP violation. In effect, the plaintiff often alleges the firm restated and thus violated GAAP, citing APB 20, and did not report its interim financial statements in accordance with GAAP, citing APB 28. To the extent that these violations are boilerplate and without substance, including them in our analysis could bias our results, especially given that their RBC score is relatively low. Therefore, we conducted a robustness test in which we excluded APB 20 and APB 28 in calculating the average RBC score of each case. After excluding these standards, our results remain statistically significant at the 0.01 level and also remain economically significant.

*, **, *** Indicate significant differences across groups at the 0.10, 0.05, and 0.01 levels, respectively (two-tailed).
Panel A displays descriptive statistics for lawsuits involving restatements and potential lawsuits involving a restatement that were not filed. We obtain lawsuit data from the RiskMetrics Securities Class Action Services database, complaints from the Stanford Securities Class Action Clearinghouse, and restatements without lawsuits (potential suits not filed) from the 1997–2006 GA0 sample. We do note, however, that the Riskmetrics data do not contain data on the dollar magnitude of the settlement for two restatement lawsuits. Thus, we have data on the magnitude of the settlement for 137 of the 139 restatement lawsuits that were settled. We performed t-tests of differences across groups. Variables are defined in Appendix B.

Panel B reports the 15 most common standard violations or alleged violations obtained from filed lawsuits and potential lawsuits involving restatements. Our sample of lawsuits involving a restatement was obtained from the Securities Class Action Services database. Our sample of restatements that could have potentially resulted in a suit was obtained from the 1997–2006 GAO sample and includes instances where the firm's restatement announcement caused the firm's market value to drop by at least $50 million dollars. The RBC score of these standards is also presented. The RBC score measures whether a standard contains bright-line thresholds, scope and legacy exceptions, large volumes of implementation guidance, and a high level of detail. *RBC* increases by 1 when a standard contains any one of the above-mentioned criteria. *RBC* is calculated each year for each standard because standards change over time as detail, exceptions, and implementation guidance are added. The RBC score reported is the median RBC score over 1996–2006, the sample's time period. The table is sorted by RBC score.

Panel C reports the results of a logistic regression investigating the impact of rules-based characteristics on the decision to file a lawsuit when the firm admits to violating GAAP (restatement lawsuit). In Equation (1), *F* is the cumulative distribution function of the logistic distribution. We utilize the *RBC* measure from Mergenthaler (2010), which increases by 1 when a standard contains any one of the four following criteria: (1) bright-line thresholds, (2) scope and legacy exceptions, (3) large volumes of implementation guidance, and (4) a high level of detail. Our sample of 189 firms with a restatement where a lawsuit was filed between 1996 and 2005 was obtained from the Securities Class Action Services database. Our sample of 84 restatements where a lawsuit was not filed was obtained from the 1997–2006 GAO sample

(continued on next page)

TABLE 3 (continued)

and includes instances where the firm's restatement announcement caused the firm's market value to drop by at least \$50 million dollars. The "All Lawsuits" sample includes 189 restatements with lawsuits and 84 restatements without lawsuits, for 273 total observations. The "Settled Lawsuits" sample includes 139 restatements where the lawsuit was settled (out of the 189 total restatements with lawsuits) and the entire sample of 84 restatements without lawsuits, for 223 total observations. The "Dismissed Lawsuits" sample includes 50 restatements where the lawsuit was dismissed (the remainder of the 189 total restatements with lawsuits) and the entire sample of 84 restatements without lawsuits, for 134 total observations. t-statistics are in parentheses. All variables that lie below (above) the 1st (99th) percentiles are winsorized. The marginal effects are calculated for each observation in our sample and then averaged over all the observations (Greene 2003).

Lawsuit Filing Regression

Panel C of Table 3 reports results from estimating Equation (1). The first set of columns presents results for the combined sample of all 189 restatements with lawsuits and 84 restatements without lawsuits. *RBC* is strongly negatively related to the probability of filing a lawsuit (t-statistic $= -5.73$, $p < 0.01$), consistent with the innocent misstatement defense of the protection theory in H2. The marginal effects tabulated in Panel C suggest that a one-unit increase in *RBC* decreases the likelihood of litigation by 12.1 percentage points. This effect is both statistically significant and economically meaningful. For example, the likelihood of being sued decreases, on average, by approximately 12 percentage points when a company violates SFAS 52, which has an *RBC* of 1, versus violating SFAS 5, which has an RBC score of 0. Overall, results for the restatement sample provide support for the protection theory, suggesting rules-based standards decrease litigation risk by providing an "innocent misstatement" defense for restatements.

Robustness Tests for H2

Presence of Fraud versus Errors

We next consider whether differences in the underlying nature of the violation between our treatment and control samples drive the results in the first set of columns of Panel C in Table 3. For example, our treatment sample of restatement firms with lawsuits could consist primarily of clear-cut cases of fraud, while our control sample could primarily represent obvious errors unlikely to trigger lawsuits. To address this concern, we perform two analyses that involve modifying our sample to assess whether differences in the nature of the violation drive our results.

First, we divide the 189 restatements with lawsuits into 139 settled lawsuits and 50 dismissed lawsuits and re-estimate Equation (1) after retaining all 84 control observations for both of the subsamples. Settled suits represent cases where the court found a strong inference of fraud, while dismissed suits represent cases in which the court did not find a strong inference of fraud. Thus, the settled cases are more credible accounting fraud cases *ex post*, while the dismissed cases are more likely to include errors. We include both sets of results for comparison. The second and third set of columns of Panel C in Table 3 present the results. The strong negative relation between *RBC* and the filing of a lawsuit remains in both subsamples, with similar estimated economic magnitudes of -12.3 percent for settled cases in the "Settled Lawsuits" column and -13.4 percent fordismissed cases in the "Dismissed Lawsuits" column, with $p < 0.01$ in each case. Thus, the negative loading on *RBC* remains even when we partition our sample to separate more clear-cut cases of accounting fraud from cases that may represent errors. Specifically, the comparison of restatements without lawsuits to dismissed cases indicates that a clear separation between fraud and errors does not drive our results.

Second, in Table 4 we report results from a sample of 131 accounting irregularity firms from Mergenthaler (2010), all of which were investigated by the SEC for questionable accounting

This table reports the results of analyses that examine whether our main results from Equation (1) are robust to an alternate specification. In this analysis we use a sample of restatements that were investigated by the SEC from Mergenthaler (2010). This classification scheme is similar to that employed by Hennes et al. (2008) to identify accounting irregularities; thus, this analysis looks at whether rules-based standards impact the likelihood of litigation when the analysis is confined to accounting irregularities. t-statistics are in parentheses. All variables that lie below (above) the 1st (99th) percentiles are winsorized. Variables are defined in Appendix B.

practices. Some of these firms were named in a class action lawsuit and some were not. Given that the SEC investigated these firms, the concern that non-sued observations represent obvious accounting errors is mitigated.[19] The relation between *RBC* and the filing decision is still significantly negative in this specification ($p < 0.01$).

Taken together, the results in Tables 3 and 4 suggest that differences in the nature of the violation in terms of frauds versus errors between the control and treatment samples do not drive our findings. Instead, it appears that plaintiffs tend to avoid filing lawsuits for violations of rules-based standards even when a potential argument for fraudulent intent exists. The key is that plaintiffs must be able to persuade the court that a *strong* inference of fraud exists, which is likely difficult with violations of rules-based standards due to the innocent misstatement defense.

---

[19] We do not utilize this sample as our primary sample due to the conflicting incentives of the SEC and plaintiffs' lawyers. As we discussed in Section II, plaintiffs' lawyers are motivated by potential settlement size (Coffee 2006), which is why we screen on potential damages in our primary analysis.

Transaction Complexity and Standard Age

An additional concern with our findings is that perhaps the *RBC* measure picks up factors other than rules-based characteristics of accounting standards. For example, it is possible that the complexity of the underlying transactions, not just rules-based accounting standards, contributes to our results. As a practical matter, accounting standards tend to be more rules-based when transactions are more complex (Nelson 2003). In addition, when inferring intent, courts appear to consider both the complexity of the accounting standards (e.g., *In re Microstrategy, Inc. Securities Litigation*, 115 F. Supp. 620, 652 (E.D. Va. 2000)) and the complexity of the underlying transaction (e.g., *In re Bristol-Myers Squibb Securities Litigation*, 312 F. Supp. 2d 549, S.D.N.Y. (2004)). The negative relation between *RBC* and lawsuit filings in Table 3 could therefore be due to either the complexity of rules-based standards, the complexity of the underlying transactions associated with rules-based standards, or both.

We explore this issue by developing multiple proxies for transaction complexity. Our first proxy for transaction complexity involves searching each standard for three root words: (1) complex*, (2) complic*, and (3) elaborat*. If any of these words are found in the standard, then we read the surrounding paragraph to determine if the standard mentions the underlying transaction as complex. We then create an indicator variable that is equal to 1 if the standard refers to the underlying transaction as complex, and is equal to 0 otherwise. Untabulated analysis indicates that this indicator variable categorizes 35 percent of the underlying transactions in our sample as complex. For example, the following standards involve complex transactions using this proxy: (1) SFAS 133 (derivatives), (2) APB 14 (convertible debt), (3) SFAS 13 (leases), (4) SFAS 109 (taxes), and (5) SFAS 87 (pensions). Finally, since many of the 273 restatements in our sample involve more than one standard (and thus more than one underlying transaction), we calculate the mean of this indicator variable for each of the 273 restatements. This procedure yields our first complexity measure, which we label *COMPLEXITY_1*.

Our second proxy for transaction complexity (*COMPLEXITY_2*) is the mean of the number of words contained in the definition of the underlying transactions involved in each restatement. We obtain definitions from the glossary of the FASB Codification. For example, for SFAS 13, the measure counts the number of words needed to define a lease under the assumption that it will take more words to describe complex transactions. We utilize the log of this measure to mitigate skewness.[20]

Table 5 presents our analyses designed to isolate the effects of transaction complexity from *RBC*. In Column (1) of Table 5, we include *COMPLEXITY_1* as a covariate in our lawsuit filing analysis. After including this variable, the *RBC* coefficient remains negative and significant at the 0.01 level (t-statistic = −4.17). Interestingly, the *COMPLEXITY_1* coefficient is also negative and significant, suggesting that both transaction complexity and the rules-based nature of the standard affect the decision to file a class action lawsuit. Column (2) of Table 5 reports the results using our second measure of complexity (*COMPLEXITY_2*) as a covariate, and we find that *RBC* remains significantly negative at the 0.01 level (t-statistic = −5.71) while *COMPLEXITY_2* is also significant at the 0.01 level. Consistent with Column (1), these results suggest that both *RBC* and transaction complexity affect the filing decision, presumably because both complex rules and complex transactions make it more difficult to infer fraudulent intent.[21]

---

[20] Thirteen of the 273 restatements in our sample involve no underlying transaction and deal exclusively with accounting issues (e.g., how to calculate EPS or report changes in accounting policies). For these observations, we assign them the lowest transaction complexity score obtained from all other restatements that have an underlying transaction. We do this because these restatements are not likely impacted by transaction complexity. We also re-ran our analysis after dropping these observations. Our results are unchanged using this alternative specification.

To assess the economic significance of *RBC* relative to our measures of transaction complexity, we calculated standardized regression coefficients as well as marginal effects for a one standard deviation change in either *RBC* or our two transaction complexity measures. In untabulated results, we found that a one standard deviation increase in *RBC* has roughly a 147 percent (25 percent) bigger reduction in the probability of being sued compared to our first (second) complexity measure. Thus, it appears *RBC* has a larger economic effect on the probability of being sued compared to transaction complexity. However, we caution that perfectly separating the complexity of rules-based standards from the complexity of underlying transactions is difficult to achieve from an empirical standpoint. Nevertheless, the tests above do indicate that our results do not appear to be driven exclusively or even predominantly by transaction complexity.

Finally, in the last column of Table 5, we include the average age of the standards violated as an additional covariate. In general, there has been an increase in *RBC* across all standards over time (untabulated). At the same time, newer standards, for example for derivatives, stock options, pensions, etc., tend to involve more complex transactions and to have higher RBC scores. As such, the significance of *RBC* could be related to standard age, but the results in Column (3) of Table 5 do not support this conjecture. Although the results suggest that violations of older standards are more likely to trigger lawsuits, *RBC* remains significantly negatively related to lawsuit incidence ($t = -4.79$).

Other News and Revenue

We perform two additional untabulated robustness checks for our restatement sample. First, we exclude observations involving earnings announcements within three days of the restatement announcement to avoid confounding our filing model with other news. Excluding these observations does not change the economic or statistical significance of our results. Second, we also found significantly negative coefficients on *RBC* both among restatements involving revenue and restatements not involving revenue. This finding suggests that the relation between *RBC* and the probability of litigation is significant in both revenue and non-revenue cases.

Test of H3

To test the effect of rules-based standards on litigation outcomes, we first estimate the following logistic regression:

$$Prob(Meritorious = 1) = F\Big(\alpha + \beta_1 RBC + \beta'(Controls)\Big). \tag{2}$$

Meritorious is a dichotomous variable coded 1 if the lawsuit reaches a meritorious outcome as defined below. We again include firm size and profitability as control variables since larger, more profitable firms may have access to better legal counsel and may be more successful in preventing a meritorious outcome. As discussed above, the outcome of the suit hinges on the perceived strength of the case and ability to prove scienter. Thus, we include variables based on plaintiffs' complaints

---

[21] We also re-ran our primary analysis excluding SFAS 13 and SFAS 133 violations to ensure that they do not drive our results. These standards are generally viewed as extremely rules-based standards and involve complex underlying transactions. This leads to a common perception that these standards often result in unintentional errors in their application. Untabulated results are very similar when these observations are excluded. We also found that violations of SFAS 13 (leases) and SFAS 109 (taxes) are clustered in our sample during the years of 2003–05. The clustering appears to be related to regulatory enforcement by the SEC (SFAS 13) and new internal control assurances provided as a result of SOX (SFAS 109). Our inferences are also unchanged when this pair of standards is omitted from our analyses.

This table reports the results of analyses that examine whether transaction complexity or the age of the standard drive our main results from Equation (1). In Column (1), we include our first complexity measure, *COMPLEXITY_1*, as an additional covariate. *COMPLEXITY_1* is a dummy variable that is equal to 1 when the transaction is described as complex, and is equal to 0 otherwise. We identify transactions described as complex by reading the paragraphs in the standard that contain the following root words or their derivatives: (1) complex*, (2) complic*, or (3) elabor*. In Column (2), we include an alternative proxy for complexity, *COMPLEXITY_2*, which is defined as the natural log of the length of the definition used to describe the underlying transaction that the standard pertains to. If the standard has no underlying transaction (e.g., FAS 128, which outlines how to calculate EPS), then we input the lowest transaction complexity score recorded for all other standards that had an underlying transaction. We do this because standards without an underlying transaction are not impacted by transaction complexity and their complexity score should thus be low because there really is no impact from transaction complexity. Finally, Column (3) includes the age of the standard as an additional covariate. All variables that lie below (above) the 1st (99th) percentiles are winsorized. Variables are defined in Appendix B.

that are plausibly positively related to the ability to prove scienter, including whether: (1) the firm's auditor was named as a defendant, (2) insider trading was alleged, (3) revenue manipulation was alleged, (4) an external whistleblower, such as the press, is mentioned in uncovering the alleged fraud, (5) an internal (i.e., board of directors) or external (i.e., SEC) investigation has taken place, (6) top executives have resigned during or after the class period, and (7) the auditor has resigned. We also include announcement stock returns and the maximum potential damage as a proxy for the extent to which fraud can be inferred. Finally, we include indicator variables for high litigation risk industries and whether the case alleges a violation of Section 11 of the 1933 Securities Act.

*, **, *** Denote significance at the 0.10, 0.05, and 0.01 levels, respectively (two-tailed).

This table reports the results of examining the impact of rules-based characteristics on lawsuit outcomes. Columns (1) and (2) report the results of a logistic regression exploring the impact of rules-based characteristics on two proxies for meritorious outcomes, while Column (3) reports the results of an OLS regression examining the impact of rules-based characteristics on the magnitude of settlement amounts. Column (1) utilizes the dismissal decision as a proxy for a meritorious outcome. A suit that survives the dismissal decision is equal to 1, while a suit that is dismissed is equal to 0. Column (2) follows Johnson et al. (2007) and classifies a suit as meritorious if the settlement is at least 0.5 percent of the firm's market value of equity. Finally, Column (3) follows the Johnson et al. (2007) methodology to identify meritorious cases. Then, among the meritorious cases, it reports the results that examine the impact of rules-based characteristics on settlement amounts. Our sample of 189 suits (116 of which are termed meritorious according to the Johnson et al. [2007] methodology) was obtained from the Securities Class Action Services database. t-statistics are in parentheses. All variables that lie below (above) the 1st (99th) percentiles are winsorized. Variables are defined in Appendix B.

Table 6 contains estimates from Equation (2), using two proxies of meritorious suit outcomes. Column (1) uses the dismissal decision as a proxy, with *Meritorious* coded as 1 if the suit survives the dismissal decision, and 0 otherwise. In Column (2), we utilize the Johnson et al. (2007) measure for meritorious lawsuit outcomes, coding *Meritorious* as 1 if the settlement is greater than 0.5 percent of the firm's market value of equity, and 0 otherwise. Johnson et al. (2007) use this measure because certain cases that survive dismissal may be non-meritorious, even though the allegations were sufficient to survive a motion to dismiss. In these cases, the company may settle to avoid further litigation costs.

Inconsistent with H3, we find no significant relation between *RBC* and meritorious suit outcomes using either proxy. The insignificance of *RBC* and most other variables in Equation (2) is perhaps not surprising. Prior studies generally find that few variables help predict suit outcomes (see, Johnson et al. 2007; Pritchard and Sale 2005). The fact that many aspects of this process are unobservable or difficult to measure likely contributes to the inability of the model to explain the dismissal decision with much precision. In addition, as we discuss above, variables correlated with the strength of the case, including *RBC*, are likely to be anticipated by plaintiffs' attorneys, leading to a screening process at the filing stage. Thus, variables such as *RBC* may have little ability to predict lawsuit outcomes once weaker cases have been screened out at the filing stage.

As a final test of H3, we perform an OLS regression of settlement amounts on the covariates in Equation (2). Settlements are scaled by maximum damages during the class period and we exclude non-meritorious settlements following the Johnson et al. (2007) definition above. Results in Column (3) of Table 6 show that the coefficient on *RBC* is positive, but not significant at conventional levels ($t = 0.99$). Consistent with earlier tests, we find no significant relation between *RBC* and lawsuit outcomes.

V. LIMITATIONS

Three potential limitations merit discussion in the context of our findings. The first involves the possibility that *ex ante* litigation risk endogenously affects the rules-based characteristics of accounting standards as preparers and auditors demand more guidance in areas where litigation risk is higher. We do not attempt to model simultaneity in our data, primarily because measuring *ex ante* litigation risk across roughly 80 years of U.S. GAAP standards using only post-1996 litigation data seems infeasible. One would expect this source of endogeneity to bias the results in favor of finding a positive relation between litigation risk and rules-based accounting standards. Because we find the opposite, it does not appear that the *ex ante* effect of litigation risk on accounting standards is a significant concern for inferences in our sample.

The second limitation relates to the unobservability of key financial reporting decisions. For example, it is possible that the rules-based nature of accounting standards affects the decision to restate. Rules-based misstatements may be more easily detectable by auditors or regulators, and rules-based standards provide clear guidance that could force a firm to restate when it is outside that guidance. Both of these factors could lead to more restatements involving rules-based standards. If this is the case, then principles-based standards could help firms avoid litigation because many potential principles-based violations would be unobservable. The universe of observable misstatements (i.e., restatements) might therefore be biased toward firms with rules-based misstatements. However, the theory most relevant to this concern, the roadmap theory, predicts these rules-based misstatements should be the most likely to trigger litigation. As we find just the opposite, it does not appear this concern affects inferences in our study. Put another way, even if rules-based standards are more likely to trigger restatements, we find no evidence that these rules-based restatements increase the threat of litigation.

Other forms of unobservability are not as innocuous for our inferences. If firms choose to engage in fraudulent accounting more often in relatively principles-based areas of GAAP, then this effect could contribute to our findings. However, since the underlying incidence of fraud or earnings management is unobservable, this concern is a limitation of any archival study of litigation or earnings manipulation.[22]

The final limitation is that we do not consider all of the potential effects of a shift to a principles-based accounting system. Standard-setters are likely primarily concerned with the usefulness of information produced by the accounting system, and we do not address this issue. However, litigation is an important potential "side effect" in such a shift, particularly in the U.S. given its highly litigious nature (Schipper 2003; SEC 2003). Our consideration of litigation does not include all potential costs of a switch to principles-based standards and, thus, we cannot make a recommendation regarding whether such a switch is likely to be beneficial overall. Rather, we only provide evidence on the likely effect of rules-based standards on litigation incidence and outcomes.

---

[22] Mergenthaler (2010) provides some evidence in this area, finding that the dollar magnitude of accounting violations is larger when rules-based standards are involved. As such, this should bias against our finding that principles-based standards are more likely to lead to securities litigation.

VI. CONCLUSION AND DISCUSSION

This study provides the first systematic empirical evidence regarding the association between rules-based accounting standards and securities litigation. Our evidence is important because the U.S. Congress issued a mandate in SOX requiring the SEC to conduct a study of the cost of implementing more principles-based standards in the U.S., and the SEC (2003) specifically noted in the study that such a shift could affect the incidence of litigation. More recently, the SEC (2010) issued a proposal that would require public firms in the U.S. to adopt the more principles-based IFRS.

We utilize two samples of sued firms to test the effect of principles-based standards on the incidence of litigation. First, we compare the standards cited by plaintiffs in cases that do not involve restatements to the standards identified in each sued firm's significant accounting policies. In such cases, the protection theory predicts that plaintiffs will tend to allege standards that are more principles-based due to the safe harbor protection provided by rules-based standards when firms follow the rules, as well as plaintiffs' ability to "second-guess" accounting decisions under principles-based standards. We find evidence consistent with the prediction of the protection theory, that rules-based standards provide a "safe harbor" and are thus not often cited in lawsuits.

Second, using a sample of restatements, we find that violations of rules-based standards are associated with a lower probability of litigation. This finding is inconsistent with assertions that violations of rules-based standards provide plaintiffs with a "roadmap" to successful suits. Rather, it is consistent with the protection theory in that complex, rules-based standards provide firms with an "innocent misstatement" defense. This relation remains economically and statistically significant after controlling for transaction complexity and is robust to a variety of alternative specifications.

In summary, our evidence suggests that rules-based accounting standards reduce the threat of litigation. However, the overall effects of a shift to a more principles-based accounting system are difficult to predict because "the U.S. litigation system and accounting practices [would] transition to a new equilibrium" and numerous factors would change simultaneously (Hail et al. 2010, 377). Thus, while we are leery of definitively predicting a shift in the equilibrium level of securities litigation should the U.S. shift to a more principles-based accounting system, our findings do offer insight for policymakers.

First, our evidence is consistent with the notion that increasing the extent of principles-based accounting standards would weaken safe harbor protection and give plaintiffs a wider menu of potential "judgment-based" allegations in cases not involving an admitted misstatement. This would increase the threat of litigation for firms. Second, decreasing the extent of rules-based accounting standards might make the "innocent misstatement" defense less credible given an accounting restatement, and also increasing the threat of litigation. However, increasing the extent of principles-based accounting standards could also reduce the number of restatements in general, but this development may have little effect since we find that rules-based restatements pose a relatively low litigation threat in the current legal environment. Finally, we emphasize that the U.S. court system already has built-in protections against frivolous securities litigation through the PSLRA. Thus, any increase in the threat of litigation from a switch in accounting standards may be at least partially mitigated by these protections.

APPENDIX A

EXAMPLE OF SUMMARY OF SIGNIFICANT ACCOUNTING POLICIES FROM 10-K AND LAWSUIT ALLEGATIONS

POLICY MANAGEMENT SYSTEMS CORP, 12/31/1999
NOTE 1. SUMMARY OF SIGNIFICANT ACCOUNTING POLICIES

ARB 51 (*RBC* = 3), APB 18 (*RBC* = 3)
BASIS OF PRESENTATION

The consolidated financial statements are prepared on the basis of generally accepted accounting principles and include the accounts of the Company and its majority owned subsidiaries (collectively, the "Company"). All material intercompany balances and transactions have been eliminated. The equity method of accounting is used when the Company does not have effective control and has a 20 percent to 50 percent interest in other companies. Under the equity method, original investments are recorded at cost and adjusted by the Company's share of undistributed earnings or losses of these companies.

SFAS 5 (*RBC* = 1)
USE OF ESTIMATES

The preparation of financial statements in conformity with generally accepted accounting principles requires management to make estimates and assumptions that affect the reported amounts of assets and liabilities and disclosure of contingent assets and liabilities at the date of the financial statements, as well as the reported amounts of revenues and expenses during the reporting period. Actual results could differ from those estimates. Financial statement line items that include significant estimates include the allowance for uncollectible receivables, accrued revenues, accrued restructuring charges, goodwill and other intangibles, net, capitalized software and costs, net, and income tax balances.

CON 5-6 (*RBC* = 1), SOP 97-2 (*RBC* = 2), ARB 45 (*RBC* = 0)
REVENUE RECOGNITION

The Company's revenues are generated primarily by licensing software systems and providing outsourcing and professional services to the global insurance and related financial services industries. All revenues are recorded in accordance with Statement of Position 97-2, *Software Revenue Recognition* (SOP 97-2), and Statement of Position 81-1, *Accounting for Performance of Construction-Type and Certain Product-Type* **Contracts (SOP 81-1). [Note: details of revenue**

recognition omitted for brevity. Also, SOP 81-1 provides interpretive guidance related to ARB 45 (percentage of completion accounting), so we use that standard to calculate *RBC*.]

CASH AND CASH EQUIVALENTS

The Company considers all highly liquid investments with an original maturity of three months or less to be cash equivalents.

SFAS 115 (*RBC* = 3), SFAS 107 (*RBC* = 1)
MARKETABLE SECURITIES

Debt securities included in the Company's investment portfolio for which there is a positive intent and ability to hold to maturity are carried at amortized cost. Debt securities that may be sold prior to maturity and all marketable equity securities are classified as available-for-sale and carried at fair value. The fair value is estimated based on quoted market prices for those or similar investments. Net unrealized gains and losses, determined on the specific identification method, on securities classified as available-for-sale are carried as a separate component of accumulated other comprehensive income.

Realized gains and losses are included in net income and the cost of securities sold is based on the specific identification method. Marketable securities were sold for cash proceeds of $2.1 and $3.3 million during 1999 and 1998, respectively. There were no sales of marketable securities during 1997.

ARB 43-9b (*RBC* = 0), ARB 43-9c (*RBC* = 0)
PROPERTY AND EQUIPMENT

Property and equipment, including support software acquired for internal use, is stated at cost less accumulated depreciation and amortization. Property and equipment is depreciated on a straight-line basis over its estimated useful life.

Gains and losses on dispositions of property and equipment are determined based on the difference between the cash plus the fair value of any assets received (in the case of nonmonetary transactions) less the net book value of the asset disposed of at the date of disposition.

APB 17 (*RBC* = 1), SFAS 121 (*RBC* = 1)
GOODWILL AND OTHER ACQUIRED INTANGIBLE ASSETS

Identifiable intangible assets and goodwill are recorded and amortized over their estimated economic lives or periods of future benefit. The lives established for these assets are a composite of many factors that are subject to change because of the nature of the Company's operations. This is particularly true for goodwill that reflects value attributable to the going-concern nature of acquired businesses, the stability of their operations, market presence, and reputation. Accordingly, the Company evaluates the continued appropriateness of these lives and recoverability of the carrying value of such assets based upon the latest available economic factors and circumstances. The Company evaluates the recoverability of all long-lived assets, including specific intangible assets and goodwill, based upon a comparison of estimated future cash flows from the related operations with the then corresponding carrying values of those assets. Impairment of value, if any, is recognized in the period in which it is determined. A rate considered to be commensurate with the risk involved is used to discount the cash flows for any recognized impairment.

The Company amortizes goodwill over an estimated life of 3 to 15 years. Other identifiable purchased intangible assets are being amortized on a straight-line basis over their estimated period of benefit ranging from 3 to 10 years.

SFAS 86 (*RBC* = 1) SOP 98-1 (*RBC* = 1)
CAPITALIZED SOFTWARE COSTS

In accordance with Statement of Financial Accounting Standards No. 86, *Accounting for the Costs of Computer Software to Be Sold, Leased or Otherwise Marketed* (SFAS 86), certain costs incurred in the internal development of computer software and costs of purchased computer software, consisting primarily of software acquired through business acquisitions, are capitalized. **[Note: details omitted for brevity.]**

The Company also capitalizes certain costs in accordance with Statement of Position 98-1, *Accounting for the Cost of Computer Software Developed or Obtained for Internal Use* (SOP 98-1). **[Note: details omitted for brevity.]**

SFAS 109 (*RBC* = 4)
INCOME TAXES

The provision for income taxes and corresponding balance sheet accounts are determined in accordance with Statement of Financial Accounting Standards No. 109, *Accounting for Income Taxes* (FAS 109). Under FAS 109, the deferred tax liabilities and assets are determined based on temporary differences between the basis of certain assets and liabilities for income tax and financial reporting purposes. These differences are primarily attributable to differences in the recognition of depreciation and amortization of property, equipment and intangible assets and certain software development costs and revenues.

SFAS 128 (*RBC* = 3)
BASIC AND DILUTED EARNINGS PER SHARE

Basic and diluted earnings per share (EPS) are calculated according to the provisions of Statement of Financial Accounting Standards No. 128, *Earnings per Share* (FAS 128). Weighted average common shares outstanding for all periods have been restated to reflect the stock split in June 1998 (see Note 11). For the Company, the numerator is the same for the calculation of both basic and diluted EPS. The denominator for basic and diluted EPS is the same for the period ended December 31, 1999 as the loss from operations would otherwise cause the inclusion of common stock options to be anti-dilutive. The following is a reconciliation of the denominator used in the EPS calculations (in thousands):

> Weighted average shares for 1999 would have included 1,174,358 common stock equivalents if the Company had recorded net income. All options to purchase shares of common stock were included in the computation of diluted EPS for 1998.

SFAS 52 (*RBC* = 2)
FOREIGN CURRENCY TRANSLATION

The local currencies of the Company's foreign subsidiaries have been determined to be their functional currencies. Assets and liabilities of foreign subsidiaries are translated into United States dollars at current exchange rates and resulting translation adjustments are included as a separate component of accumulated other comprehensive income. Revenue and expense accounts of these operations are translated at average exchange rates prevailing during the year. Transaction gains and losses, which were not material, are included in the results of operations of the period in which they occur.

The effect on the Company's operating revenues of adverse foreign currency exchange fluctuations (stated as current year international revenues translated at prior year average exchange rates) was $4.3 and $8.0 million for 1999 and 1998, respectively.

RBC of significant accounting policies: 1.59

Summary of Lawsuit

This case was triggered by a series of bad news announcements in late 1999 and early 2000. The Company announced a variety of write-downs and special charges during this time frame. Plaintiffs alleged, among other things, that the financial statements during the class period violated GAAP in that these write-offs and charges should have been recorded sooner and were deliberately deferred to increase share price. Plaintiffs also alleged that software revenue was recorded improperly. The case settled for $7.75 million after the motion to dismiss was denied by the court.

Lawsuit Allegations of GAAP Violations

SFAS 5 (contingencies) *RBC* = 1
SFAS 86 (capitalization of software costs) *RBC* = 1

APPENDIX B

Variable Definitions

Note: For firms that were not sued, the "class period" is defined as the time period between the earnings announcement date of the first misstated quarterly period and the restatement announcement date.

AGE = the age of the accounting standard in years, based upon initial passage;
ANN_RET = cumulative return for the seven days centered on the restatement announcement date or class period end date, expressed as a percentage;
AUDITOR_NAMED = indicator variable that is equal to 1 when the auditor is named in the complaint, and is equal to 0 otherwise;
AUDITOR_RESIGN = 1 if the auditor resigns during the class period, and is equal to 0 otherwise;
BIG4 = indicator variable equal to 1 if the auditor code from Compustat is between 1 and 8;
COMPLEXITY_1 = indicator variable equal to 1 if the relevant accounting standard describes the underlying transaction using any of the three root words: (1) complex*, (2) complic*, and (3) elaborat*, and 0 otherwise;
COMPLEXITY_2 = log of the number of words contained in the definition of the underlying transaction addressed by each accounting standard; we obtain definitions from the glossary of the FASB Codification;
DISMISS = indicator variable equal to 1 if the suit is dismissed;
INSIDER = average monthly net insider selling over the class period, from Thomson Reuters, scaled by total shares outstanding, expressed as a percentage;
INSIDER_SALE = 1 when the plaintiff alleges insider selling activities, and 0 otherwise;

INVESTIGATE_EXTERN = indicator equal to 1 when the complaint indicates that there was an external investigation, and is equal to 0 otherwise;

INVESTIGATE_INTERN = indicator equal to 1 when the complaint indicates that the company conducted an internal investigation, and is equal to 0 otherwise;

ISSUE = indicator variable equal to 1 when the firm issues stock during the class period (Compustat data item SCF), and is equal to 0 otherwise;

LIT_RISK = indicator variable that is set to 1 when the firm operates in a high litigation risk industry (see Francis et al. 1994), and is equal to 0 otherwise;

LN_MAX_DAMAGE = natural logarithm of the *MAX_DAMAGE* variable;

MAX_DAMAGE = highest market value of the firm during the restatement period minus the market value of the firm on the restatement disclosure date (in millions);

MERITORIOUS = indicator variable set to 1 if the suit is meritorious, defined as either (a) a lawsuit that is not dismissed, or (b) a lawsuit that settles for more than 0.5 percent of the defendant firm's market value of equity;

MVE = market value of equity at the end of the quarter preceding the end of the class period;

RBC = average rules-based continuum score of the standards alleged to have been violated. The rules-based continuum score increases by 1 when the standard contains bright-line thresholds, scope and legacy exceptions, voluminous implementation guidance, or a high level of detail. The minimum value of *RBC* is 0 and the maximum is 4. *RBC* is calculated each year for each standard because standards change over time as detail, exceptions, and implementation guidance are added. See Mergenthaler (2010) and Table 1 for further details;

REVENUE = indicator variable equal to 1 if the plaintiff alleged that revenue was misstated, and is equal to 0 otherwise;

ROA = earnings before extraordinary items (as originally reported) for the quarter preceding the end of the class period, scaled by total assets, expressed as a percentage;

SEC_11 = indicator variable that is equal to 1 when the complaint indicates a Section 11 violation, and is equal to 0 otherwise;

SETTLEMENT = dollar amount of the settlement in the lawsuit;

SHARE_TURN = average daily turnover (volume/shares outstanding) over the class period, expressed as a percentage;

SIZE = log market value of equity at the end of the quarter preceding the end of the class period;

SUED = indicator variable equal to 1 if the restatement resulted in a class action lawsuit, and is equal to 0 otherwise;

VOLATILITY = standard deviation of daily returns over the class period, expressed as a percentage; and

WHISTLE = indicator variable that is set to 1 when the complaint mentions an external whistle blower, and is equal to 0 otherwise.

City-Level Auditor Industry Specialization, Economies of Scale, and Audit Pricing

Simon Yu Kit Fung

Jagan Krishnan
Temple University

ABSTRACT: We examine the effects of city-level auditor industry specialization and scale economies on audit pricing in the United States. Using a sample of Big N clients for the 2000–2007 period, and a scale measure based on percentile rankings of the number of audit clients at the city-industry level, we document significant specialization premiums and scale discounts in both the pre- and post-Sarbanes-Oxley Act (SOX) periods. However, the effects of industry specialization and scale economies on audit pricing are highly interactive. The negative effect of city-industry scale on audit fees obtains only for clients of specialist auditors. By contrast, clients of non-specialist auditors obtain scale discounts only when they enjoy strong bargaining power, suggesting that auditors are "forced" to pass on scale economies to clients with greater bargaining power.

Keywords: *industry specialization; scale economies; audit pricing; client bargaining power.*

Data Availability: *Data are available from sources identified in the article.*

I. INTRODUCTION

In this study, we investigate the effects of city-level audit-firm industry specialization and scale economies among Big 5 (4) auditors (hereafter, Big N auditors) on audit pricing in the United States. We focus on Big N auditors because they dominate the audit market in the U.S. This

domination has two outcomes, namely, industry specialization due to the expertise developed from expanding within industries, and economies of scale arising from spreading audit investment costs over a large client base. Academic research has examined the effects of industry specialization and, to a much lesser extent, the effects of scale economies, on audit pricing.

Our investigation is relevant for three reasons. First, recent research has emphasized that the local (city) offices of the Big N are the primary units of decision-making (Ferguson et al. 2003; Francis et al. 2005), and are responsible for determining fee contracts (Francis et al. 1999). It is therefore important that researchers investigate the pricing effects of city-level industry specialization and scale economies. However, studies that have conducted city-level analyses have focused on the city-level specialization premium without controlling for city-level scale differences.[1] Our examination of the U.S. audit market reveals significant differences in scale at the city level among the Big N, although their national operations are relatively more evenly divided.[2] If these scale economies generate cost savings that are passed on to clients, then there should be cross-sectional variation in the observed fee premiums resulting from city-level specialization. Hence, we attempt to identify the separate effects of city-level industry specialization and city-level scale economies on audit pricing.

Second, it is important to examine whether (and in what settings) the benefits of scale economies are passed on to clients, particularly in light of concerns that the Big N audit firms dominate the audit market.[3] In its most recent report on this issue, the Government Accountability Office (GAO) states that "market participants ... raised concerns that splitting up these firms could reduce their economies of scale and the depth of expertise that currently allow the largest firms to effectively and efficiently audit large companies" (GAO 2008, 6). Evidence on the effects of scale economies on the fees charged to audit clients is therefore of interest to regulators, auditors, and market participants.

Third, as we discuss in the next section, not only is there an absence of studies that examine city-level scale economies, but also the studies that examine national-level scale economies employ data from the 1980s or 1990s (with the exception of Fields et al. [2004], who use year 2000 data). The audit market has undergone dramatic changes during the past decade, particularly since the enactment of the Sarbanes-Oxley Act (SOX) of 2002. These changes include the move from self-regulation to quasi-governmental regulation of the accounting profession, new audit requirements (Section 404 of SOX, in particular), a proscription on providing a number of nonaudit services in conjunction with audit services, increased requirements for audit committee interaction with auditors, and changes in other disclosure and management reporting requirements (Krishnan and Yang 2009). Several studies have documented changes in the magnitude and structure of audit fees over the years surrounding SOX (e.g., Griffin and Lont 2007; Ghosh and Pawlewicz 2009). Because industry specialization premiums and scale discounts contribute to the structure of audit fees, it is important to investigate their effects in the new audit environment.

---

[1] As we discuss later, a few studies examine the audit-pricing effects of national-level scale economies. For example, Mayhew and Wilkins (2003) examine a sample of IPO firms for the 1991–1997 period and find that, after controlling for industry product differentiation (measured at the national level), audit fees are negatively associated with industry-based economies of scale. Some studies (e.g., Gist 1994; Fields et al. 2004) examine the role of scale economies in specific industries.

[2] The average national market share (based on client audit fees) for Big 4 auditors is 0.25 during our sample period, and ranges from 0.22 (for KPMG) to 0.29 (for PwC), suggesting that their national operations are evenly distributed.

[3] The Sarbanes-Oxley Act of 2002 (SOX) required the Government Accountability Office (GAO) to study the impact of audit firm consolidation "on competition, including the availability of auditor choices ... on the cost, quality, and independence of audit services" (GAO 2003, 2). The GAO (2003) concluded that due to the reduction in the number of audit firms, clients seeking industry specialists in some industries end up having only two audit firms from which to choose.

We examine the city-industry scale economies that arise from expansion within industries at the city level, as industry-specific training and other costs are spread over many clients (Mayhew and Wilkins 2003). Using a large sample of Big N clients in the 2000–2007 period, we find significant variation in the city-industry scale in the U.S. audit market. For example, in 2003, PricewaterhouseCoopers (PwC) was the industry specialist for the electrical and electronic equipment industry (i.e., standard industry classification code 36) in both San Jose and in Orange County, California, with 47 and 4 clients, respectively, in that industry (source: Audit Analytics). Therefore, PwC's industry specialization in San Jose was 11.75 times larger in city scale than that in Orange County, for the same year and same industry.

We examine whether city-industry scale differences have an impact on audit pricing. Because scale economies arise from expanding operations within a market (i.e., the city-industry audit market), we construct our city-industry scale measure as the percentile rank of the number of audit clients for each Big N auditor in city-industry combinations in each year. We test for the effects of our scale measure on audit fees, after controlling for auditor industry specialization.

For differences in scale to have an impact on audit pricing, two conditions must be met. First, the increase in scale must generate cost savings as the auditor expands within city-industries and, second, some or all of these savings must be passed on to clients.[4] Ideally, therefore, we must employ data on audit costs at the city-industry level to ascertain directly the existence of scale economies. However, in common with all researchers in this area, we do not have such cost information. Consequently, we rely on proxies for scale economies to make inferences about their impact on audit pricing. We acknowledge that interpretation of our results is linked to our measure of scale.

Consistent with prior research, our results indicate that industry specialist auditors (i.e., city-industry leaders) earn significant premiums (14.8 percent, or $226,000, on average) compared to non-specialist auditors. In addition, scale discounts are also prevalent throughout our sample period.[5] Evaluated at the sample mean, audit fees decrease by 1.7 percent (or $25,900) for a one-decile increase in city-industry scale. However, we find the effects of industry specialization and economies of scale on audit pricing to be highly interactive. The negative effect of city-industry scale on audit fees applies only to industry specialist auditors, and the audit fee premium for industry specialization is smaller for auditors with a larger city-industry scale. These results suggest that industry specialization and economies of scale are not independent forces affecting audit fees.

We also document interesting differences between the pre- and post-SOX periods: the auditor industry specialization premiums are higher in the latter period, although scale discounts are slightly smaller. However, the aforementioned interactive effects hold in both periods.

Because an auditor's incentive to charge a premium or to pass on scale economies is likely to depend on the relative bargaining power it enjoys *vis-à-vis* its clients (Mayhew and Wilkins 2003; Casterella et al. 2004), we examine whether client bargaining power moderates the effects of specialization and scale on the specialist/non-specialist premium. We find client bargaining power exerts a moderating effect on both the specialization premium and the scale discount. Both specialist and non-specialist auditors pass on some scale discounts to clients with a high degree of bargaining power. However, only specialist auditors pass on scale discounts to clients with a relatively low degree of bargaining power. Thus, our results suggest that auditors are "forced" to pass on scale economies when their clients enjoy greater bargaining power.

---

[4] Note that we do not argue that there is a consistent link between audit fees (price) and cost, that is, that consistent margins are made on each audit, in each industry, at each office, of each audit firm. Instead, we acknowledge that cost savings may be passed on differentially across clients. If there are no scale economies, then we would not expect our scale measure to affect audit pricing. Likewise, the absence of an association between scale and audit pricing would not necessarily indicate the absence of scale economies; it could also mean that these economies are not passed on to clients.

[5] As we report later, these findings are robust to alternative specifications of our scale measure.

Although we focus on the scale economies that arise from expansion of auditor operations within industries in cities, scale economies can also arise more generally as the auditor expands operations within a city, regardless of the industry. In additional analysis, we examine these *city-level* scale economies rather than the *city-industry* scale economies presented as our main analysis. The results are similar to our main findings.

We contribute to an understanding of audit pricing by the Big N auditors in a number of ways. First, we add to current knowledge about the pricing effects of city-level auditor industry specialization by showing that scale effects moderate the extent of the specialization premium. Second, to the best of our knowledge, we are the first to document that city-industry-specialization premiums have increased in the post-SOX period. Possible explanations for this increase are that the perceived benefits are viewed as being higher in an environment of greater scrutiny and litigation concerns and/or that the marginal benefit of specialization is greater now, because specialists are able to conduct better Section 404 audits. Third, our finding that auditors pass on scale economies to clients provides some support for the GAO's (2008) observation that there is little evidence of Big N oligopolistic pricing. However, we also find that in some situations, for example, in which the client has a low degree of bargaining power *vis-à-vis* a non-specialist auditor, the latter's city-scale has no effect on audit pricing. Fourth, we focus on differences within Big N auditors, rather than Big N/non-Big N differences, which is particularly relevant given the dominance of Big N auditors in the audit market.

In Section II, we discuss the study's background and develop our research questions. Section III discusses the sample selection and research method. The results are discussed in Sections IV and V, and Section VI concludes.

II. BACKGROUND AND RESEARCH QUESTIONS

Prior Research on Auditor Industry Specialization and Audit Fees

Panel A of Table 1 presents a summary of prior studies that examine the fee impact of industry specialization at the national, city, and global levels. Studies that employ national-level specialization measures yield mixed results. Palmrose (1986) finds no evidence for the existence of a specialization premium in the U.S. Using survey data from 1993, Casterella et al. (2004) document a Big 6 industry specialization premium for the small client segment of the U.S. market, but not for the large client segment. By contrast, Carson and Fargher (2007) identify a premium for large, but not for small, client firms in the Australian market. Huang et al. (2007) replicate the Casterella et al. (2004) study for the years 2000, 2001, 2003, and 2004, similarly documenting a specialization premium only for the small client segment, in both the pre- and post-SOX periods, with the exception of 2003 in which they find no such premium. They speculate that 2003 is "perhaps a unique year due to the flux in the audit market following the enactment of SOX" (Huang et al. 2007, 147). Using data from Hong Kong and Australia, DeFond et al. (2000) and Craswell et al. (1995), respectively, document the presence of a premium, whereas Ferguson and Stokes (2002), using more recent Australian data, do not. At the international level, Carson (2009) examines global audit networks employing samples of firms from more than 60 countries, finding significant fee premiums for global specialists.

Recent studies have shifted attention to city-level auditor industry specialization based on the rationale that the primary audit work and decision-making involving clients occurs in the local offices of the Big N auditors (Francis et al. 2005). Consequently, city offices are likely to be better units for analyses of audit outcomes than national offices. Of the three studies listed in Table 1,

TABLE 1

Evidence from Prior Studies on the Specialization Premium and Economies of Scale

Panel A: Specialization Premium

Studies (1)	Data Characteristics (2)	National-Level Industry Specialization Premium[a] (3)	City-Level Industry Specialization Premium (4)
U.S. Data			
Palmrose (1986)	U.S. data; 1980–1981; Big 8 and non-Big 8 auditors (n = 361); Questionnaire-based study	No specialist premium	NA
Francis et al. (2005)	U.S. data; 2000–2001; Big 5 auditors (n = 3,994)	No specialist premium	City-level and joint city-national-level industry specialization premium
Casterella et al. (2004)	U.S. data; 1993; Big 6 auditors (n = 651); Survey data	Specialists earn a premium only for small companies in the sample	NA
Huang et al. (2007)	U.S. data; 2000, 2001, 2003, 2004 (n = 4,619)	Specialists earn a premium only for small companies in the sample except in year 2003	NA
International Data			
Craswell et al. (1995)	Australian data; 1987; Big 8 and non-Big 8 auditors (n = 1,484)	Specialists earn a premium	NA
Ferguson and Stokes (2002)	Australian data; 1990, 1992, 1994, 1998; Big 6/5 and non-Big 6/5 auditors (n = 955)	Limited support for the existence of specialist premium	NA
Ferguson et al. (2003)	Australian data; 1998; Big 5 auditors (n = 1,046)	No specialist premium	City-level and joint city-national-level industry specialization premium
DeFond et al. (2000)	Hong Kong data; 1992; Big 6 and non-Big 6 auditors (n = 225)	Specialists earn a premium for Big 6 clients	NA
Carson and Fargher (2007)	Australian data; 1998 (n = 558) (primary sample); 1999 and 2004 (sensitivity tests) (n = 1,154)	Specialists earn a premium in largest clients size quintile	City-industry leaders earn a premium in largest size
Carson (2009)	Sample from 62 countries in 2000 (n = 15,583) and 60 countries in 2004 (n = 14,628)	Global specialists earn a premium	NA
Studies Using Specific Settings or Industries			
Mayhew and Wilkins (2003)	U.S. IPO firms; 1991–1997; Big 6 auditors (n = 2,294)	Industry leader earns a premium	NA

(continued on next page)

TABLE 1 (continued)

Studies (1)	Data Characteristics (2)	National-Level Industry Specialization Premium[a] (3)	City-Level Industry Specialization Premium (4)
Fields et al. (2004)	U.S. Financial institutions; 2000; Big 5 and non-Big 5 (n = 277)	No specialist premium	NA
Pearson and Trompeter (1994)	U.S. insurance companies 1982–1986; Big 8 auditors (n = 241)	No specialist premium	NA

[a] The dependent variable in all of these studies is the (log of) audit fee (except in Mayhew and Wilkins [2003], who use accounting fees reported in IPO filings), because of the unavailability of audit fees for IPO firms.

Panel B: Discount from Scale Economies

Studies (1)	Data Characteristics (2)	Discount from National-Level Economies of Scale (3)	Discount from City Level Economies of Scale (4)
International Data			
DeFond et al. (2000)	Hong Kong data; 1992; Big 6 and non-Big 6 auditors (n = 225)	Fee discount for clients of a non-Big 6 firm in the property industry	NA
Studies Using Specific Settings or Industries			
Mayhew and Wilkins (2003)	U.S. IPO firms; 1991–1997; Big 6 auditors (n = 2,294)	Fee discount for greater industry market share (if not an industry leader)	NA
Gist (1994)	U.S. data; 5 regulated and 5 nonregulated industries; 1983–1985; Big 8 and non-Big 8 auditors (n = 263)	Fee discount (using client regulatory complexity as measure of EOS)	NA
Fields et al. (2004)	U.S. financial institutions; 2000; Big 5 and non-Big 5 (n = 277)	Fee discount (using proportion of clients and proportion of assets audited)	NA
Pearson and Trompeter (1994)	U.S. insurance companies 1982–1986; Big 8 auditors (n = 241)	Fee discount (using concentration ratio)	NA

Panel A that address city-level industry specialization, Ferguson et al. (2003), using Australian data, and Francis et al. (2005), using U.S. data, document that city-level industry specialists earn a premium over non-specialists.[6] However, Carson and Fargher (2007), using Australian data, find that, as with their national-level results, the specialization premium holds only for large clients at the city level.

---

[6] In addition to city-level specialization, both Ferguson et al. (2003) and Francis et al. (2005) document that joint city-national specialists also earn fee premiums. However, national-level specialization alone does not result in a fee premium.

Prior Literature on Economies of Scale and Audit Fees

Table 1, Panel B, shows the relatively short list of previous studies that discuss the pricing effects of economies of scale, all of them focused on the national level. Employing population data, DeFond et al. (2000) find evidence of scale economies for the property industry in Hong Kong. Other studies examine scale economies in specific contexts. Examining the initial public offering (IPO) setting, Mayhew and Wilkins (2003) estimate an audit-fee model in which the test variables are measures of industry specialization, proxied by industry leadership, and scale economies, proxied by the auditor's industry market share. Their results show a positive association between industry specialization and audit fees. In addition, auditors' industry share has a negative coefficient, suggesting that, after controlling for industry specialization, auditors pass on some of the benefits of economies of scale. Fields et al. (2004), Pearson and Trompeter (1994), and Gist (1994) examine the role of scale economies in the financial services industry, the insurance industry, and five regulated and five unregulated industries, respectively, finding support for the existence of scale discounts.[7]

City-Level Economies of Scale

As firms expand operations within an audit market, or within a particular industry in that market, the efficiencies stemming from economies of scale can reduce unit costs (Scherer and Ross 1990; Junius 1997).[8] A larger operation allows for the better allocation of resources, sharing of knowledge, and intrafirm networking. For an audit firm, the scale economies can arise from substantial investment in general audit technology (e.g., audit software development or hardware acquisition) and human capital development (e.g., staff training), which are likely to be shared among all of their clients. Once these investments are in place, additional clients can be serviced at a lower marginal cost than the cost of servicing the first few clients.

At the city level, larger offices also enable audit firms to specialize within industries, leading to scale economies at the industry level. Mayhew and Wilkins (2003, 35–36) provide a comprehensive discussion of how scale economies arise from industry specialization. These economies arise because industry specialization enables auditors to service a larger number of firms within an industry, as they possess similar client characteristics and service needs, thereby reducing audit costs and simultaneously increasing the "service value" provided to clients. Mayhew and Wilkins (2003, 36) attribute the decrease in costs to audit firm personnel's ability to be "adept at identifying and addressing industry-specific audit issues." Auditors are also able to reduce their incremental industry-specific training costs as their number of clients increases.

We refer to the efficiencies arising from auditors' expansion within city-industries as city-industry scale economies. If a larger city-industry scale results in cost savings (scale economies), and some or all of these savings are passed on to clients, then scale differences should produce differences in audit fees. *A priori*, we expect a larger city-industry scale to be associated with lower audit fees. For example, if auditors A and B have 20 and 4 clients, respectively, in industry X in a given city, then we would expect auditor A to have greater city-industry economies of scale than auditor B (Mayhew and Wilkins 2003). However, if a larger scale does not lower costs (i.e., there are no economies of scale), or if lower costs are not passed on to clients, then we would expect there to be no association between scale and audit fees.

---

[7] Francis and Stokes (1986) examine economies of scale in the context of the Big N premium rather than the industry specialization premium.

[8] Willenborg (2002) also points out that industry specialization (usually measured in terms of greater auditor size in the industry) enables an auditor to audit both "smarter" (with greater effectiveness) and "faster" (with higher efficiency).

Therefore, we examine whether auditors with a larger city-industry scale offer discounts to their audit clients. As a corollary, we also examine whether industry specialists charge lower specialization premiums to their audit clients if they enjoy city-industry scale economies (i.e., whether the specialization premium is moderated by scale).

Client Bargaining Power and Audit Fees

Auditors may not always pass on scale economies in the form of fee discounts. Casterella et al. (2004) and Mayhew and Wilkins (2003) argue that auditor/client bargaining power can influence audit pricing. Consequently, we examine whether the audit-pricing effects of industry specialization and scale economies are moderated by clients' relative bargaining power.

Casterella et al. (2004) define bargaining power as the auditor and client's importance to each other, and they measure it in both absolute terms (client size) and in terms of the client's importance in the auditor's portfolio. Mayhew and Wilkins (2003) employ a more restrictive definition of bargaining power, which considers the degree of differentiation. They argue that economies of scale are less likely to be passed on to the client when the differentiation is sufficiently marked as to give the auditor greater bargaining power *vis-à-vis* the client. Both studies find that client bargaining power lowers audit fees. Thus, *a priori*, we expect greater client bargaining power to decrease the industry specialization premium and increase the scale discount.

The Sarbanes-Oxley Act and Audit Fees

In addition to our focus on city-level specialization and scale economies, we also note that our use of a recent sample period constitutes an important extension of the prior research, because the audit market has undergone dramatic changes over the past decade, particularly after the enactment of SOX. The accounting profession has moved from self-regulation to independent regulation by the Public Company Accounting Oversight Board (PCAOB), which has assumed the standard-setting process for the audits of public companies and has instituted an inspection process for accounting firms (Kinney 2005). In addition, several changes introduced by SOX have also affected auditors, either directly by changing the audit requirements or indirectly by changing the corporate governance or management reporting requirements. Section 404 of the Act, which requires audits of clients' internal control over financial reporting in conjunction with financial statement audits, constitutes a major change in the audit process (Dickins et al. 2008). Section 201 bans the provision of many nonaudit services that had traditionally been provided by CPA firms to their audit clients. Section 301 empowers audit committees to appoint auditors, set their compensation, and oversee the audit process. SOX requirements have also increased the degree of communication between audit committees and auditors (Krishnan and Yang 2009).[9]

These changes have affected both the magnitude and structure of audit fees. Griffin and Lont (2007) and Ghosh and Pawlewicz (2009) show significant increases in audit fees during the post-SOX period. Other studies show fee increases resulting from SOX Section 404 (Raghunandan and Rama 2006; Hogan and Wilkins 2008; Hoitash et al. 2008). Fleming and Romanus (2007) provide evidence of a negative association between industry specialization and audit fee changes in the first year following SOX Section 404 implementation, but find no effect in subsequent years. They attribute this one-time negative association to the ability of industry specialist auditors to conduct more efficient internal control audits because of their superior knowledge of clients' accounting and internal control systems. Some studies show structural changes in audit fees. For example, Ghosh and Lustgarten (2006) and Ghosh and Pawlewicz (2009) document changes in fee-cutting in the pre- and post-SOX environments. Francis and Wang (2005) show that the disclosure of audit fees in proxy filings (starting in 2001) resulted in a change in the precision of audit pricing. In addition, to the extent that audit and nonaudit fees are simultaneously determined (DeFond et al. 2002; Whisenant et al. 2003), it is possible that the proscription of nonaudit services could have caused changes in the determinants of audit fees.

---

[9] Other SOX requirements include CEO and CFO certifications, reconciliation of non-GAAP financial measures, and additional disclosures concerning SPEs (Griffin and Lont 2007). During the post-SOX period, there were also many accounting and auditing standards issued by the PCAOB and FASB. See Krishnan and Yang (2009) for a discussion.

These changes could also have caused changes in auditors' industry specialization premiums and/or scale discounts. The demise of Arthur Andersen likely caused adjustments in the city-industry specializations of the remaining auditors. Increased audit demands and capacity constraints, arising both from Arthur Andersen's withdrawal as a supplier of audit services and the new SOX requirements, could have caused further modifications in client portfolios, adding to potential changes in city-industry portfolios. Heightened litigation concerns could also have increased specialization premiums if the perceived benefits of auditor specialization were amplified by those concerns.

Scale discounts may have been affected due to both changes in cost structures that generate cost savings and to factors that determine whether the savings will be passed on to clients. Factors likely to have changed the underlying cost structure include the removal of many nonaudit services that were previously provided in conjunction with audit services and the introduction of integrated audits of internal controls and financial statements. The increased transparency of audit fee disclosures could also have increased scale discounts if auditors' ability to withhold these discounts was reduced. However, the demise of Arthur Andersen reduced auditor choice for clients, which could also have had implications for auditor competition and scale discounts. Due to these conflicting forces, we expect that the changed audit environment is likely to have had an impact on both specialization and scale effects, although the direction of these impacts cannot be predicted.

Summary of Research Questions

In sum, we pursue four research questions. First, we examine whether, in addition to city-industry specialization, city-industry scale affects audit pricing. All else being equal, we expect a greater city-industry scale to be associated with lower audit fees. Second, we examine whether the city-industry specialization premium is moderated by auditors' city-industry scale, implying that auditors would give up some part of the premium if there are scale effects. Third, we examine whether client bargaining power affects the city-level specialization premium and scale discount. Fourth, and finally, we examine differences in the specialization premium and scale discount in the pre- and post-SOX periods.

III. DATA AND RESEARCH METHOD

Sample

Table 2 presents the sample screening procedures. We start with all U.S. publicly listed companies with Big N auditors for which fee data for the 2000–2007 period are available on the Audit Analytics database, yielding 57,596 firm-year observations.[10] We then exclude: (1) firms unavailable on Compustat (15,552); (2) firms in the financial sector (10,927); (3) foreign firms (2,664); and (4) firms with missing Compustat data (2,237). These exclusions leave a total of

---

[10] In common with other studies in this area, our data pertain to publicly listed companies, thus ignoring the specialization or scale effects of private clients. We acknowledge this as a limitation.

TABLE 2
Sample Selection

Screening	
Big N observations with audit fee data for 2000–2007 on Audit Analytics	57,596
Less:	
Companies not available on Compustat	(15,552)
Financial Sector (SIC Codes 6000–6999)	(10,927)
Foreign firms	(2,664)
Missing Compustat data	(2,237)
Missing auditor city information	(929)
City-industry-year combinations with less than two observations, or with only one Big N auditor	(8,080)
Final Sample Size	17,207

26,216 firm-year observations. In addition, because both industry expertise and auditor scale are identified at the city level, we exclude: (5) observations for which auditor city information is unavailable (929); and (6) observations for city-industry-year combinations for which there are fewer than two companies and cities with only one Big N auditor (8,080).[11] Hence, the final sample, which includes 54 two-digit SIC industries, consists of 17,207 firm-year observations, with the number of annual observations varying between 1,637 and 2,600.

Empirical Model

Following Francis et al. (2005), we estimate the following regression model to test our research questions:

$$\begin{aligned} LAF = {} & \beta_0 + \beta_1 Spec + \beta_2 Scale + \beta_3 CITYSIZE + \beta_4 LTA + \beta_5 LSEG + \beta_6 CATA + \beta_7 QUICK \\ & + \beta_8 DE + \beta_9 ROI + \beta_{10} FOREIGN + \beta_{11} OPINION + \beta_{12} YE + \beta_{13} LOSS \\ & + \beta_{14} AAClients + Fixedeffects + \varepsilon, \end{aligned} \tag{1}$$

where:

LAF = natural log of audit fees (in thousands of dollars);
$Spec$ = indicator variable coded 1 for auditors that are city industry leaders, and 0 otherwise;
$Scale$ = percentile rank of the city-industry number of audit clients (*NClients*) for each Big N audit firm (variable values range from 0.01 to 1);
$CITYSIZE$ = natural log of aggregate audit fees for all firms audited by the company's auditor for each city;
LTA = natural log of total assets (in millions of dollars);

---

[11] Following Francis et al. (2005), we exclude city-industry-year combinations with less than two observations because of the possibility of measurement error in the auditor city designation, and because it is unlikely to be a competitive audit market for city-level industry specialization if there is only one client in the industry for the city. We delete cities with only one Big N auditor to better identify specialists. We are concerned that, in cities in which there is only one Big N auditor, this auditor would automatically be the specialist. As a sensitivity test, we re-run our models on a sample of 20,391 observations in which the city has only one Big N auditor. The results are similar to those reported.

LSEG = natural log of the number of unique business segments;
CATA = ratio of current assets to total assets;
QUICK = ratio of current assets (excluding inventories) to current liabilities;
DE = ratio of long-term debt to total assets;
ROI = ratio of earnings before interest and tax to total assets;
FOREIGN = proportion of total sales from foreign operations;
OPINION = indicator variable coded 1 for modified audit report, and 0 otherwise;
YE = indicator variable coded 1 for non-December 31 year-end, and 0 otherwise;
LOSS = indicator variable coded 1 if loss in current fiscal year, and 0 otherwise;
AAClients = indicator variable coded 1 if there was an auditor change and the predecessor audit firm in year t–1 was Arthur Andersen, and 0 otherwise;
Fixedeffects = year and industry indicator variables; and
ε = random-error term.

City-Industry Specialization Measure

Following Francis et al. (2005), we use audit fees to construct the specialization variables. We first compute each Big N audit firm's share in each two-digit industry group in each city, and then rank the auditors from 1 to 5 based on their city-level industry share.[12] The auditor with the largest share is designated the industry specialist (*Spec* = 1). The untabulated mean (median) difference in the market share of the industry specialist auditor and its closest competitor is 35.8 percent (32 percent) in our sample. The first quartile of the difference is 11.6 percent, indicating that, for the majority of the sample, the top two auditors are not very close in terms of market share.[13]

Table 3, Panel A, presents a summary of the number of city-industries in which each of the five auditors is an industry specialist. Not surprisingly, Arthur Andersen has the lowest number (212), because it is in our sample for only the first two years (2000–2001). The other four auditors' specialist status ranges from 835 city-industries for KPMG to 1,230 city-industries for PwC.

City-Industry Scale Measure

Unlike auditor industry specialization measures, which are widely used in the literature, proxies for scale economies are less commonly employed. The traditional measures of scale economies used in the economics literature require cost data (Scherer and Ross 1990).[14] However, these data are not generally available in the auditing context, and our measure of scale economies is thus indirect. Because scale economies are generated by expanding operations within a market (i.e., the city-industry), we base our measure on the number of clients. To construct our city-level scale measure, we first compute *NClients* (the number of clients the auditor has in each city-industry

---

[12] Because of the demise of Arthur Andersen in 2002, our sample includes the Big 5 in 2000–2001 and the Big 4 in 2002–2007. As we report later, we include a variable for Andersen clients in our regressions to control for this change.

[13] In sensitivity analysis, we delete observations for which the difference between the market shares of the leading and second auditor is 5 percent or less, and re-run the regressions. The results are very similar to those reported later in our main findings. In another sensitivity test, we also define "specialist" based on a 20 percent (25 percent) market share threshold for 2000–2001 (2002–2007). The results are similar to our main findings.

[14] These measures include the price-cost margin, Lerner index (price minus marginal cost divided by price), minimum efficient plant size, and cost elasticities (e.g., Bain 1956; Waring 1996; Paul and Siegel 1999; see Junius [1997] for a review). Some studies of the financial services industry construct measures of scale economies using data from Compustat (e.g., Zacharias 2008; Hao 2009). For example, studies of the banking industry employ data on expenses along with measures of output to estimate the parameters of a production function and, therefore, economies of scale (Berger and Mester 1997).

TABLE 3

Distribution of Specialist and Scale Measures

Panel A: Specialist Status of Auditors: The Number of City-Industry Combinations for which the Auditor is a Specialist

Auditor	2000	2001	2002	2003	2004	2005	2006	2007	Total
AA	97	115							212
DT	72	112	147	138	124	123	130	128	974
EY	110	138	186	183	166	144	139	143	1,209
KPMG	73	99	131	124	125	102	101	80	835
PwC	114	162	196	174	168	159	134	123	1,230
All	466	626	660	619	583	528	504	474	4,460

Panel B: Number of Clients Audited at the City-Industry Level (*NClients*)

Auditor	Mean	Q1	Median	Q3
AA	15.73	4.00	8.00	21.00
DT	13.14	4.00	7.00	16.00
EY	14.77	4.00	8.00	20.00
KPMG	11.02	3.00	6.00	14.00
PwC	18.65	4.00	9.00	27.00
All	14.94	4.00	8.00	20.00

AA = Arthur Andersen;
DT = Deloitte;
EY = Ernst & Young;
KPMG = KPMG; and
PwC = PricewaterhouseCoopers.

combination) for each year. We rank *NClients* across all city-industry combinations. *Scale* is the percentile rank of *NClients* across all city-industry combinations for each year; its values range from 0.01 to 1.[15] The percentile transformation is desirable because *NClients* is highly skewed (Table 3, Panel B). Alternative specifications, such as *NClients* in raw form or in its logarithmic transformation, yield results similar to those reported below.

In the auditing literature, national-level scale measures (see Table 1, Panel B), include the proportion of clients audited (Fields et al. 2004) and the proportion of clients' assets audited

---

[15] To illustrate, consider the following example. The number of clients (*NClients*) in 2001 for each Big 5 auditor in two-digit SIC industry 73 (business services) in Boston and two-digit SIC industry 28 (chemicals and allied products) in Philadelphia are as follows: Boston = 25, 23, 10, 7, 7; Philadelphia = 8, 6, 5, 1, 1. To construct *Scale*, we convert the city-industry numbers (i.e., 25, 23, 10, 8, 7, 7, 6, 5, 1, 1) into percentile ranks for each year. We use the PROC RANK procedure in SAS to do this, but because the procedure produces ranks between 0 and 99, we add 1 to the ranks generated by it to obtain ranks between 1 and 100. Thus, *Scale* takes the value of 0.91 (the SAS-generated rank + 1 scaled by 100) for the auditor in Boston with 25 clients, and 0.14 for the auditors in Philadelphia with one client. Note that we do not construct the measure within each city-industry combination, as doing so could lead to undesirable results. For example, using the foregoing numbers, if we ranked auditors within each city-industry combination, then we would have two large-scale auditors (25 and 8), although 8 is a relatively small-scale operation. With our measure, an auditor with eight clients in a city-industry would be considered a relatively small-scale auditor, regardless of where it operates.

(Mayhew and Wilkins 2003). However, these market share-based measures are not conducive to city-level analysis. For example, a 50 percent share in city-industry A could comprise five clients, whereas a 50 percent share in city-industry B could comprise 25 clients. By contrast, our measure provides uniform scaling across all city-industry combinations. We later report sensitivity tests using these alternative measures of scale, pooling them across city-industry combinations, as we do with our primary measure.

Table 3, Panel B, presents the distribution of *NClients*, which forms the basis for our scale variable. We observe considerable variation in the number of clients that each auditor has across city-industry combinations. The interquartile range for the number of clients in city-industry combinations varies from 11 for KPMG to 23 for PwC.

Control Variables

We include control variables based on previous studies. Recent studies (Francis and Yu 2009; Choi et al. 2010) suggest that larger city offices provide higher quality audits. Francis and Yu (2009) find larger Big N offices to be more likely to issue going-concern audit reports and clients in larger offices to be associated with less aggressive earnings management. Choi et al. (2010) find that office size is positively associated with audit fees, which is consistent with the quality-differentiation argument. Therefore, we include *CITYSIZE*, measured as the (logarithm of) aggregate audit fees for all firms audited by the company's auditor for each city.

Other control variables, following Francis et al. (2005), include firm size (*LTA*), audit opinion (*OPINION*), a variable indicating a December fiscal year-end (*YE*), and measures of firm complexity and audit risk. The firm-complexity variables are the number of business segments (*LSEG*) and the extent of foreign operations (*FOREIGN*). The audit-risk variables include *CATA*, *DE*, *LOSS*, *QUICK*, and *ROI*. We also include *AAClients* to examine the incremental effect on audit fees for auditor changes involving Arthur Andersen. Finally, we include year and industry indicator variables.[16]

IV. RESULTS

Univariate Analyses

The descriptive statistics for all variables, which are reported in Table 4, are generally comparable with those reported in previous studies (e.g., Francis et al. 2005). The mean (median) audit fee is $1,525.34 thousand ($559.61 thousand).[17] Correlations between the variables are presented in Panels B and C of Table 4. All correlations between independent variables are less than 0.5, except for those between *ROI* and *LOSS* (–0.57) and between *LTA* and *CATA* (–0.52).[18]

---

[16] The year indicator variables serve to control for the numerous policy changes that occurred during our sample period, particularly the changes necessitated by SOX Sections 302 and 404.

[17] This is a higher figure than that in some prior studies. For example, Francis et al. (2005) report that the mean (median) audit fee is $502,000 ($196,000). We attribute the discrepancy to the fact that the sample period in Francis et al. (2005) covers the first-time fee disclosures during 2000–2001, whereas our sample includes the post-SOX years 2002–2007, during which audit fees are known to have increased (Ettredge et al. 2007). For our 2000–2001 observations, the mean (median) audit fee is $558,000 ($202,000), which is close to the mean (median) figure in Francis et al. (2005).

[18] We re-run our models after eliminating *ROI*, *LOSS*, *LTA*, and *CATA* (one at a time), and the results remain unchanged. *CITYSIZE* is positively correlated with *Scale*, although neither the magnitude of the correlation (0.35) nor the VIF values for the two variables raise serious concerns about multicollinearity. Nevertheless, we examine the effects of alternative forms of *CITYSIZE* (i.e., an indicator variable for large and small city size and quartile and quintile rankings) on our results. In all cases, the results are similar to those reported.

TABLE 4
Descriptive Statistics

Panel A: Sample Statistics (n = 17,207)

Variable	Mean	Median	Std. Dev.	Q1	Q3

p-values (two-tailed) are reported in parentheses.

Variable Definitions:
Audit fees = audit fees (in thousands of dollars);
LAF = natural log of audit fees (in thousands of dollars);
Assets = total assets (in millions of dollars);
LTA = natural log of total assets (in millions of dollars);
SEG = number of unique business segments;
LSEG = natural log of the number of unique business segments;
CATA = ratio of current assets to total assets;
QUICK = ratio of current assets (excluding inventories) to current liabilities;
DE = ratio of long-term debt to total assets;
ROI = ratio of earnings before interest and tax to total assets;
FOREIGN = proportion of total sales from foreign operations;
OPINION = indicator variable coded 1 for modified audit report, and 0 otherwise;
YE = indicator variable coded 1 for non-December 31 year-end, and 0 otherwise;
LOSS = indicator variable coded 1 if loss in current fiscal year, and 0 otherwise;
AAClients = indicator variable coded 1 if there was an auditor change and the predecessor audit firm in year *t*−1 was Arthur Andersen, and 0 otherwise;

(continued on next page)

TABLE 4 (continued)

CITYSIZE = natural log of aggregate audit fees for all firms audited by the company's auditor for each city;
Spec = indicator variable coded 1 for auditors that are city industry leaders, and 0 otherwise;
Scale = percentile rank of the city-industry number of audit clients (*NClients*) for each Big N audit firm (variable values range from 0.01 to 1); and
Power = percentile ranks of bargaining power measure computed as the natural log of company sales divided by the sum of the natural log of sales for all firms audited by the company's auditor for each city-industry combination (variable values range from 0.01 to 1).

Multivariate Analyses

Table 5, Panel A, reports the results from estimating Equation (1). We cluster standard errors by year and two-digit SIC industry (Petersen 2009; Gow et al. 2010) to address potential problems associated with the non-independence of the panel observations.[19] The adjusted R^2 is 0.79, and the control variables are statistically significant in the expected directions, comparable to those reported by Francis et al. (2005).[20]

Consistent with Francis et al. (2005), the coefficient on *Spec* is positive and significant ($p < 0.01$). In addition, the coefficient on *Scale* is negative and significant ($p < 0.01$). The coefficient values indicate that, all else equal, a specialist charges a 14.8 percent higher audit fee than a non-specialist. A one-decile increase in scale is associated with a 1.7 percent decline in audit fees. This suggests that, on average, a larger-scale auditor at the city-industry level is likely to pass on a portion of the scale economies to its audit clients by charging a lower audit fee.

Because our sample period is marked by many changes in the financial and regulatory environment that could have affected audit fee patterns, we also estimate the regression for the pre- and post-SOX periods and for each of our sample years. Panel B of Table 5 presents the estimates for the pre- and post-SOX periods. Interestingly, both the specialization premium and scale discount exist in both periods, although the former is significantly stronger in the post-SOX period, as indicated by the F-test ($p < 0.01$). All else being equal, the specialization premiums are 9.5 percent and 16.2 percent in the pre- and post-SOX periods, respectively. The coefficients for *Scale* for the two periods indicate that the scale discount is significantly weaker in the post-SOX period ($p < 0.01$). However, the magnitude of the difference in the scale discount between the two periods is not as large as the difference in the specialization premium. A one-decile increase in city-scale is associated with a decline in audit fees of 1.8 percent in the pre-SOX period and 1.6 percent in the post-SOX period. Thus, whereas the increase in the importance of the specialization premium appears to be both statistically and economically significant, the decrease in the scale discount is statistically significant but is not as economically significant.

Table 5, Panel C, presents the yearly coefficients for *Spec* and *Scale*. The specialization premium is significant throughout the period and, as in Panel B, generally higher in the post-SOX period. The scale discount is also significant in all years except 2006, for which the p-value is 0.11.

Alternative Measures of Scale

Table 5, Panels D and E, presents alternative versions of our scale measure, based on the proportion of clients audited (Fields et al. 2004) and the proportion of clients' assets audited

---

[19] As an alternative approach to dealing with non-independent observations, we also test the significance of our coefficients using the Fama-MacBeth statistic, and the results are similar to those reported.

[20] One interesting result is that the coefficient on *AAClients* is negative and significant, suggesting that Arthur Andersen-related auditor changes are associated with a lower audit fee.

(continued on next page)

TABLE 5 (continued)

Scale: p-value = (< 0.01).

The models in Panels C, D, and E are estimated with all control variables and year and industry fixed effects. Only the variables of interest are reported for brevity. p-values (two-tailed) are reported in parentheses, which are based on robust standard errors clustered by firm.

See Table 4 for other variable definitions.

(Mayhew and Wilkins 2003). We compute these two alternative measures at the city-industry level and construct percentile rankings of auditors, similar to our *Scale* measure. For brevity, we do not report the coefficients for the control variables. The results are similar to those in Panels A and B. Both measures suggest the existence of a significant specialization premium and a significant scale discount for the full sample, as well as for the pre- and post-SOX periods.[21] In addition, as previously discussed, alternative functional forms of our primary scale variable, such as the raw number of clients (*NClients*) and the logarithm of the number of clients, yield similar results.[22]

Interaction between *Spec* and *Scale*

In Table 6, we examine whether there are interactions in the effects of *Spec* and *Scale*. That is, is the scale discount more likely to be passed on when there is a significant specialization premium? We present an augmented model, including the interaction *Spec* × *Scale*, for the full sample (Columns 1–2), the pre-SOX period (Columns 3–4), and the post-SOX period (Columns 5–6).

The coefficient on *Spec* is positive and statistically significant in all three regressions, indicating the presence of a specialization premium even in the absence of scale effects. However, the coefficient on *Scale* is insignificant, and the interaction *Spec* × *Scale* is significant and negative ($p < 0.01$ in Column 2). Thus, scale discounts are passed on to clients only when the auditor enjoys a specialist premium. The coefficient estimates in Column 1 yield a specialization premium of 14.8 percent, estimated at the median value of *Scale*. In addition, an increase in an auditor's city-industry scale by one decile lowers the specialization premium by 3.8 percent.[23]

To explore potential nonlinearities in the interactive effects of *Spec* and *Scale*, we estimate an extended model including three variables—indicating specialists in large offices (*SpecLargeoff*), specialists in small offices (*SpecSmalloff*), and non-specialists in large offices (*nonSpecLargeoff*)—using the median value of *Scale* to demarcate large and small offices. We find that specialists in both large and small offices earn an industry specialization premium (i.e., both *SpecLargeoff* and *SpecSmalloff* are positive and significant), but specialists in larger offices earn a lower premium than their counterparts in smaller offices, and the difference is significant (F-value = 106.5, $p < 0.01$, untabulated). However, for non-specialists, the audit fees are the same regardless of office size (i.e., *nonSpecLargeoff* is not significant), suggesting that only specialists in large offices are likely to pass on the scale discounts to their clients.

---

[21] The sample size in Table 5, Panel E (for *Scale* defined using proportion of clients' assets audited) is smaller than in other tables because of the unavailability of asset information on Audit Analytics (the database used to compute our *Scale* measures) due to fewer city-industry combinations for which *Scale* can be computed.

[22] We also test an alternative scale measure based on audit fees, measured by the percentile rank of auditors' city-industry-level sum of total audit fees. We find this variable to be positively related to audit fees. We note, however, that the use of a fee-based measure for economies of scale is problematic in our study because the dependent variable is a fee-based measure (log of audit fee). Our identification of industry specialists (*Spec*) is also based on audit fees.

[23] Denoting the coefficients on *Spec* and *Spec* × *Scale* by a and b respectively, the specialization premium is given by $[\exp(a + b \times Scale) - 1]$. Further, denoting the mean value of *Scale* by *MScale*, we estimate the premium at the mean value by $[\exp(a + b \times MScale) - 1]$, and the change in premium for a change in scale ($\Delta Scale$) by $\{[\exp(a + b \times (MScale + \Delta Scale) - 1] - [\exp(a + b \times (MScale) - 1)]\}$.

Fixedeffects	Included		Included		Included	
Adjusted R^2	0.795		0.751		0.778	
n	17,207		4,235		12,972	

F-tests for difference in coefficients between the pre-SOX and post-SOX periods:
Spec: p-value = (< 0.01).
Scale: p-value = (0.79).
Spec × *Scale*: p-value = (< 0.01).
Year and industry fixed effects variables are included but not reported for brevity. p-values (two-tailed) reported in parentheses are based on robust standard errors clustered by firm.
See Table 4 for variable definitions.

The results for the full sample carry over to the pre-SOX (Table 6, Columns 3–4) and post-SOX (Columns 5–6) periods. In both periods, *Spec* is significant and positive, *Scale* is insignificant, and the interaction *Spec* × *Scale* is significant and negative. Thus, the specialization premium is significantly smaller for a larger city-industry scale, but clients enjoy no scale discounts when their auditor is not a specialist.[24]

---

[24] To check whether industry leadership is an important factor in audit pricing, we exclude observations with *Spec* = 1 and define the second ranked auditor as the specialist (*Spec2*), which reduces the sample to 9,264 observations. The results are significantly weaker for *Spec2*: the coefficient drops from 0.138 (see Table 5) to 0.024, and is marginally significant ($p = 0.093$). The coefficient on *Scale* is negative and significant (coefficient = −0.180, $p < 0.01$). In the model with the interaction between *Spec2* and *Scale*, the coefficient on *Scale* is negative and significant (−0.159, $p < 0.01$), but neither *Spec2* nor the interaction term is significant. These results suggest that industry leadership is important for auditors to generate a specialization premium.

TABLE 7

Client Size, Industry Specialization, and Economies of Scale among Big N Auditors
Dependent Variable: LAF

	Below Median Client Size		Above Median Client Size	
	Estimate	p-value	Estimate	p-value
Spec	0.254	(< 0.01)	0.329	(< 0.01)
Scale	−0.079	(0.29)	0.014	(0.83)
Spec × *Scale*	−0.312	(< 0.01)	−0.330	(< 0.01)
Adjusted R^2	0.435		0.708	
n	8,604		8,603	

F-tests for difference in coefficients between below median and above median Client Size:
Spec: p-value = (< 0.01).
Scale: p-value = (0.21).
Spec × *Scale*: p-value = (< 0.01).
Client Size is measured based on client's total assets. All control variables are included but not reported for brevity. p-values (two-tailed) reported in parentheses are based on robust standard errors clustered by firm.
See Table 4 for variable definitions.

Additional Tests

City-Level Scale

Our focus above is on scale economies that arise at the city-industry level. Scale economies can also arise when an auditor expands its operations within a city, regardless of the industry.[25] In supplementary analysis, we examine the effect of these city-level scale economies, rather than the city-industry scale economies examined in our main analysis. We construct a more aggregative measure of scale, *Scalecity*, computing it at the city-level, rather than the city-industry level. The results are similar to our main findings, with the coefficient on *Spec* (*Scalecity*) being significantly positive (negative) at the 1 percent level. The specialization premium is 12.64 percent, and the decline in audit fees for a one-decile increase in scale is 2.69 percent. When we include the interaction term *Spec* × *Scalecity*, we find, as in Table 6, that the specialization premium is significantly smaller for auditors with a larger city-level scale.[26]

Differences across Client Size Groups

To assess whether our results differ across client size segments, we partition the sample into large and small client segments, using the median of *LTA* as the cutoff, and estimate the regression for each group. Table 7 shows the results for the test variables. For both size segments, *Spec* is positive, *Scale* is insignificant, and *Spec* × *Scale* is negative.[27] Thus, consistent with Table 6, specialists charge a premium that declines with *Scale*, whereas non-specialists do not offer a fee discount for increases in *Scale*. The moderating effect of *Scale* on the specialization premium is greater for large clients than for small clients ($p < 0.01$). The decline in the premium for a one-decile increase in scale is 3.37 percent (3.8 percent) for small (large) firms.

---

[25] For example, city-level scale economies can arise from general investments in audit technology, such as audit software development and hardware acquisition. Similarly, human capital development (e.g., staff training) can be shared among all of a firm's clients.

[26] Although our focus is on the effects of city-level auditor specialization and scale, we also examine whether our results hold after controlling for national-level specialization and scale. We construct national specialization (*NATSPEC*) and scale (*NATSCALE*) measures, similar to our city-level measures. We find that, after controlling for *NATSPEC* and *NATSCALE*, our results for both the effects of city-industry specialization and scale continue to hold. However, we note that because we restrict our analyses to Big N clients, the national-level measures include only four or five observations in each industry. Variability in national-level scale across the Big N is low. The Big N market shares are also less variable at the national level (see footnote 2). Therefore, we do not present the tests for *NATSPEC* and *NATSCALE*.

Effects of Auditor Changes

To examine the general effects of auditor changes, we replace *AAClients* with an indicator variable that captures all auditor changes in our sample (*AuChange*). We find that our main findings hold with the inclusion of this auditor change measure. The coefficient (p-value) on *Scale* is –0.171 (< 0.01), and that on the interaction term is –0.336 (< 0.01). The coefficient on *AuChange* is negative and significant, consistent with previous studies that show price-cutting following auditor changes. Moreover, the coefficient on *AuChange* (–0.145, $p < 0.01$) is more negative than that on *AAClients* (–0.081, $p < 0.01$). This finding suggests that, although successor auditors, in general, offer discounts to new clients, this discount is smaller for ex-Arthur Andersen clients, possibly because they are perceived to be riskier (e.g., Cahan and Zhang 2006; Blouin et al. 2007; Kohlbeck et al. 2008; Landsman et al. 2009).

V. CLIENT BARGAINING POWER

In Table 8, we examine the effect of client bargaining power on the fee effects of specialization and scale. Following Casterella et al. (2004), we construct a client bargaining-power measure (*Power*) based on the relative importance (in the city) of the audit client to the auditor, measured as the percentile rank of the natural logarithm of company sales, divided by the sum of the natural logarithm of sales for all firms audited by the company's auditor at the city-industry level.

We split the sample based on the median *Power*, and present model estimates for high- and low-*Power* subsamples.[28] The results point to one interesting finding. For the sample with strong client bargaining power (Columns 3–4), *Spec*, *Scale*, and *Spec* × *Scale* are all significant. Thus, unlike the results for the full sample in Table 6, we see that both specialist and non-specialist auditors pass on a fee discount to their clients when these clients enjoy a relatively high degree of bargaining power. The specialization premium declines by about 4.2 percent for a one-decile increase in scale. For non-specialists, the audit fee declines by 1.1 percent for a one-decile increase in scale.

For the sample with weak client bargaining power (Columns 1–2), the results are similar to those in Table 6. *Spec* and *Spec* × *Scale* are positive and negative, respectively, indicating that specialist auditors enjoy a premium, but forgo some of that premium when scale economies are present. The specialization premium declines by 3.2 percent for a one-decile increase in scale. The coefficient on *Scale* is not significant, suggesting that when their clients' degree of bargaining power is relatively low, non-specialists offer no discounts even when their operations are larger in

---

[27] Carson and Fargher (2007) use Australian data for 1998 (and 1999 and 2004 in sensitivity tests), and find differences in the specialization premium across client size groups. Following Carson and Fargher's (2007, Table 4, Column 5), we divide our sample into small, medium, and large firms. Our model is more complicated than theirs because we need to interact these categories with *Spec*, *Scale*, and their interaction. We find that the main effect (*Scale*) is stronger for larger firms, and the interaction terms (*Spec* × *Scale*) are negative and significant for all categories, consistent with the main findings. We obtain similar results when we construct our size categories (large, medium, and small) within industries, within cities, and within industry-city combinations.

[28] This measure captures the client's importance in the city-industry. To test the robustness of our findings, we also use total assets or audit fees to measure *Power*. The untabulated results are similar to our main findings.

TABLE 8

Effect of Client Bargaining Power on Industry Specialization and Economies of Scale among Big N Auditors

Panel A: Results Based on High and Low Bargaining Power—Dependent Variable: *LAF*

Spec × *Scale*	−0.231	(0.03)	−0.410	(< 0.01)	−0.262	(< 0.01)	−0.366	(< 0.01)
Adjusted R^2	0.663		0.781		0.741		0.799	
n	1,943		2,292		6,661		6,311	

F-tests for differences in coefficients between below median and above median *Power* for the pre-SOX [post-SOX] period:
Spec: p-value = (< 0.01) [(< 0.01)].
Scale: p-value = (0.23) [(0.03)].
Spec × *Scale*: p-value = (0.03) [(< 0.01)].
All control variables are included but not reported for brevity. p-values (two-tailed) reported in parentheses are based on robust standard errors clustered by year and industries.
See Table 4 for variable definitions.

scale. In addition, the coefficient on *Spec* × *Scale* is significantly more negative ($p < 0.01$) for clients with a high degree of bargaining power (−0.324) than for those with a low degree of bargaining power (−0.283).

Panel B of Table 8 reports the effect of bargaining power on the specialization premium and scale discounts separately in the pre- and post-SOX periods. For the high bargaining power sample, the results in both time periods are similar to those for the full sample in Panel A. The specialist premium is moderated by auditor scale. The premium declines by 4 and 4.1 percent in the pre- and post-SOX periods, respectively, for a one-decile increase in scale.

For the low bargaining power sample, the results for both periods indicate that the specialist premium is moderated by auditor scale. The magnitude of the moderating effect is less than that for the sample with high bargaining power: a one-decile increase in scale reduces the specialization premium by 2.8 percent and 3 percent, respectively, in the pre- and post-SOX periods. Consistent with Table 8, Panel A (Columns 1–2), the coefficient on *Scale* is insignificant in the pre-SOX period. However, in the post-SOX period (Panel B, Columns 5–6) the coefficient on *Scale* is unexpectedly positive, albeit with a marginal p-value of 0.09. In sum, specialization premiums are moderated by scale discounts in both periods and for clients with both high and low degrees of bargaining power. However, the extent of moderation is lower for the low-power subsample than for the high-power subsample. Clients who enjoy a high degree of bargaining power with non-specialist auditors obtain scale discounts in both periods.

VI. CONCLUSION

Many audit-pricing studies have documented fee premiums for industry specialist auditors, whereas a much smaller number of studies have examined and documented the discounts due to the economies of scale that accompany auditor expansion within industries.[29] In this paper, we extend the audit-pricing literature by examining auditor industry specialization premiums and scale discounts, including the way in which they are affected by client bargaining power. In line with recent developments in the literature (e.g., Ferguson et al. 2003; Francis et al. 2005), we examine city-level rather than national-level specialization and scale economies. This is particularly insightful because, although the Big N firms have large and fairly comparable national operations, their scale in individual city markets can differ significantly. Whereas previous research has examined scale economies and audit pricing for specific industries or for IPO firms, we examine a large sample of U.S. firms for a recent time period (2000–2007) in which there were significant structural changes in the audit market due to the demise of Arthur Andersen and the enactment of the Sarbanes-Oxley Act of 2002.

We document significant city-industry specialization premiums and scale discounts throughout our sample period, although the specialization premium is larger and the scale discount slightly lower in the post-SOX period than in the pre-SOX period. However, the fee effects of industry specialization and scale are highly interactive. The benefits that arise from a larger scale are passed on to clients only by specialist auditors. The clients of non-specialists do not benefit from a large scale. Further, client bargaining power plays an important role in influencing the fee effects of both specialization and scale. When clients enjoy greater bargaining power, both specialist and non-specialist auditors of a larger scale are likely to pass on the scale economy benefits to their audit clients.

The results of this study have implications for policymakers. The consolidation of audit firms from the Big 6 to the Big 5 in 1998, and then from the Big 5 to the Big 4 in 2002, has raised concerns about the lack of competition in the large-client market (GAO 2003). It is possible that this consolidation has either reduced competition and increased prices, or created efficiencies that have led to reduced prices (Sullivan 2002). Although we do not address the effect on competition of the Big 5 to Big 4 transition (see Kohlbeck et al. [2008] for further insights into the issue), our sample period covers the years both prior to and following the demise of Arthur Andersen. Our results suggest that there is some merit in the "efficiency" argument that larger firms pass on an economies-of-scale discount to their clients.

---

[29] The premium is generally supported by evidence showing that industry specialization is associated with higher audit quality, using such measures of quality as discretionary accruals or earnings response coefficients (e.g., Krishnan 2003; Balsam et al. 2003; Gul et al. 2009).

Our study is subject to several limitations. First, economies of scale relate to cost savings. However, as in other studies in this area, our scale proxy is based on the number of audit clients rather than audit costs, due to the unavailability of data on the latter. Thus, we acknowledge that our conclusions concerning the effects of scale economies are drawn from indirect evidence, i.e., price rather than cost differences, and should therefore be interpreted with some degree of caution. Second, we focus only on publicly listed companies due to lack of available data on private companies. Third, we do not attempt to examine specific factors, such as audit methodology and staff size, that could potentially affect audit efficiency directly. Although many of these factors might be captured by the audit-firm scale measures used in this study, to the extent that they are not, they could contribute to the differential scale effects enjoyed by the large accounting firms. Future research should examine the impact of changes in the scale of audit firms over time (as opposed to the cross-sectional approach taken in this study) on changes in audit fees and quality.

Identity, Incentives, and the Value of Information

ABSTRACT: We examine the impact of identity preferences on the interrelation between incentives and performance measurement. In our model, a manager identifies with an organization and loses utility to the extent that his actions conflict with effort-standards issued by the principal. Contrary to prior arguments in the literature, we find conditions under which a manager who identifies strongly with the organization receives stronger incentives and faces more performance evaluation reports than a manager who does not identify with the organization. Our theory predicts that managers who experience events that boost their identification with the firm can decrease their effort in short-term value creation. We also find that firms are more likely to employ less precise but more congruent performance measures, such as stock prices, when contracting with managers who identify little with the organization. In contrast, they use more precise but less congruent measures, such as accounting earnings, when contracting with managers who identify strongly with the firm.

Keywords: *identity; incentives; multi-task agency; performance measure congruity; performance standards.*

I. INTRODUCTION

Agency theory is one of the most important theoretical paradigms in accounting research (Indjejikian 1999; Lambert 2001). It portrays a model of human motivation in which individuals are opportunistic maximizers of personal utility, resulting in a divergence of interest between self-interested and cooperative behavior. The theory posits that, in general, imperfect signals and conflicting interests between organizational members will lead to efficiency losses and reduced firm value (Jensen and Meckling 1976). Research in behavioral economics, on the other hand, provides substantial evidence that people have pro-social preferences and are not purely self-interested (Camerer 2003). In particular, organizational research suggests that people can take an identity as a part of an organization that inclines them to support the goals of the organization (Akerlof and Kranton 2000; Van Maanen and Schein 1979).[1]

Psychologists refer to "identity" as both a person's choice of a social reference category, such as a group, community, or organization with which to identify as well as its "self-image" or personal mental model with respect to that social reference category (Akerlof and Kranton 2000). A person's identity becomes a source of motivation when individuals internalize behavioral prescriptions so that they become internal evaluative standards to which the individual feels committed to satisfy (Akerlof and Kranton 2010; Cialdini and Trost 1998). Violating internalized standards creates anxiety and discomfort (Akerlof and Kranton 2000) and can result in strong negative emotions such as guilt and loss of self-esteem (Shamir 1990; Tangney and Dearing 2004; Tracy et al. 2007). Consequently, people who take an identity as part of an organization perceive a corresponding duty to act in concert with the standards of the organization.

The possibility that people identify with an organization opens new avenues for firms to influence their employees' decisions. By issuing standards, an organization can appeal to the sense of duty in its members.[2] This study investigates the optimal design of standards, incentives, and information systems when managers identify with an organization. Specifically, we examine the impact of identity preferences on the interrelation among optimal standards, incentives, and performance-measure characteristics.

The business community recognizes the importance of identity as an essential determinant of work-related behavior. Recent studies indicate that the military, universities, consulting firms, and high-tech companies systematically engage in initiatives to influence employees' behavior via their identities (Akerlof and Kranton 2010; Alvesson and Robertson 2006; Gioia et al. 2010; Ravasi and Phillips 2011). West Point drills and routines "inculcate non-economic motives" into cadets to align their objectives with those of the U.S. Army (Akerlof and Kranton 2005, 9). Similarly, some consulting firms cultivate an elite identity to generate "affective commitment" and "responsible autonomy" such that consultants will work hard even without traditional forms of control (Alvesson and Robertson 2006, 214).

Given the importance of identities for organizational behavior, researchers have done surprisingly little work on the use of identities as a form of control (Anteby 2008). This question is an intriguing research venue for accounting researchers for two reasons. First, identity preferences may constitute a low-cost substitute for costly incentive and monitoring systems.[3] Second, and more important, identity preferences may have direct implications for the decision-influencing role of accounting because the value of accounting information for performance evaluation and compensation purposes may be reduced when agents exhibit strong identity preferences.

---

[1] Studies of directors, accountants, investments bankers, and consultants suggest that organizational members pursue "fostered and desired occupational identities" (Anteby 2008, 202; see, e.g., Covaleski et al. 1998; Golden-Biddle and Rao 1997; Ibarra 1999). Moreover, research indicates that the strength with which people identify with an organization impacts cooperation, production, commitment, satisfaction, and turnover (Hillman et al. 2008; see, e.g., Ashforth and Mael 1989; Boivie et al. 2011; Dutton et al. 1994; Foreman and Whetten 2002; Golden-Biddle and Rao 1997).

[2] For example, at the Kellogg Graduate School of Management, the dean addresses new professors and doctoral student instructors to explain what the school considers to be appropriate behavior (Casadesus-Masanell 2004, 389). More generally, Akerlof (1982) suggests that *any* labor contract includes implicit or explicit standards.

We consider an agency setting in which a principal hires an agent or manager. The principal offers a contract to the agent that includes a standard for the agent's effort level. The agent takes an identity as a part of the organization and loses utility to the extent that his actions conflict with standards issued by the organization. Empirical studies suggest that managers differ with respect to the identity they take in an organization (Boivie et al. 2011).[4] Critical events such as corporate identity initiatives or hostile takeovers can strengthen or undermine managers' identities.[5] We account for such variance in identity by considering variations in the degree to which agents internalize their organization's standards.[6]

A manager who internalizes a standard feels distress when deviating from it. This distress arises even though the manager's effort level is non-observable. Identity preferences do not reduce the disutility of effort; rather, they motivate a manager to provide effort *despite* the disutility of effort.[7] As a consequence, the manager does not fully reap the rewards of opportunism afforded by incomplete contracts. This sharply contrasts with the behavior of a classical self-interested agent who maximizes personal utility without considering the consequences for the organization.

Our model is associated with recent economic literature on guilt aversion and integrity, which has found that individuals have a basic disposition to experience distress when "disappointing people" or "breaking their own word" (Battigalli and Dufwenberg 2007; Charness and Dufwenberg 2006). Our model is also related to recent literature on work ethics (Casadesus-Masanell 2004; Carlin and Gervais 2009; Stevens and Thevaranjan 2010) that analyzes optimal employment contracts when agents experience disutility if their effort departs from a pre-defined standard set by the principal.[8]

---

[3] For example, Hillman et al. (2008, 443) argue that "the more strongly an individual identifies with the organization, the more he will work to benefit it, because he sees himself as partly defined by the organization." With respect to contracting costs, Brickley et al. (2008, 620) write that if "everyone were to voluntarily reduce opportunistic behavior . . . then the resources devoted to monitoring and enforcing exchanges could be used in more productive pursuits." In a similar vein, Akerlof and Kranton (2005, 11) state that "An employee who identifies himself as an insider in an organization needs little monetary inducement to perform a job well."

[4] Survey scales to measure organizational identification have been used and validated by Ashforth et al. (1998), Dukerich et al. (2002), and Shamir and Kark (2004), among others. Empirical studies suggest that people tend to identify more strongly with an organization the more they have "positive experiences of the organization . . . perceive that the organization possesses distinctive and positive attributes . . . perceive that the organization possesses a positive image likely to enhance their own; and . . . perceive that the organization possesses values which are positive and congruent with their own" (Empson 2004, 763–764).

[5] See Ackerlof and Kranton (2005) and Ravasi and Phillips (2011) for examples of initiatives to strengthen identity; and see Giessner et al. (2011) for examples in which takeovers undermine individual identification with the firm.

[6] Throughout the study, we assume that all actors are perfectly informed about the actors' preferences such as their risk tolerance or the extent of their identification with the organization.

[7] Therefore, the notion of identity differs from the concept of intrinsic motivation based on needs for self-actualization (Maslow 1954), competence (White 1959), personal growth (Alderfer 1972), flow stimulation (Csikszentmihalyi 1975), self-determination (Deci and Ryan 1985), or achievement (McClelland 1988). Whereas an intrinsically motivated manager derives pleasure from performing an activity, a manager motivated by identity preferences does not necessarily enjoy performing the activity *per se*. Rather, the manager is motivated by a sense of duty or obligation toward the organization.

[8] Existing studies have also considered other motives as to why people adhere to standards. Kandel and Lazear (1992), Daido (2004, 2006), and Fischer and Huddart (2008) analyze models in which social norms are enforced by peer pressure. In their settings, norms can be subject to moral hazard and can therefore influence the optimal design of an organization. Conversely, in our study, standards are set by the principal and cannot be manipulated by agents. Furthermore, agents abide by standards because they identify with an organization and not because peer pressure forces them to do so. Hence, contrary to models of social norms and peer pressure, we analyze agents who *voluntarily* act within self-imposed confines.

These studies show that, in a single-task setting, contracts that account for an agent's nonmonetary preferences generally employ weaker incentives than the standard agency model. However, the information system in these studies reflects a single exogenous performance measure. This modeling choice abstracts away the relative usefulness of different performance measures and their incentive properties for the agent. Clearly, these issues become more important in settings in which agents engage in multiple activities. We attempt to add to the literature by investigating single- and multi-task settings with information systems that can produce multiple performance measures. This allows us to analyze the relative importance of performance-measure characteristics, the optimal incentive mix for a manager, and the value of incremental decision-influencing information for contracting purposes. Our study extends prior literature by investigating the impact of a manager's identity preferences on the organization's incentive system *and* its information system.

Our main findings are that if managers face a single task, then incentive rates and the value of additional reports for performance evaluation strictly decrease in the strength with which a manager identifies with the organization. This result matches common intuition and arguments made in the literature. In a multi-task setting, however, we find conditions under which a manager who identifies strongly with the organization receives stronger incentives and faces more performance evaluation reports than a manager who identifies less with the organization.[9]

We discuss applications of our theory and derive empirical predictions for settings in which managers significantly differ in their degree of identity or experience critical events that boost or undermine their identification with the firm. Our model predicts an inverse U-shaped relation between the number of performance measures and the strength of a manager's identity. Specifically, firms that inspire a strong (but not too strong) identity are more likely to use a mix of performance measures than less inspiring firms. Furthermore, firms are more likely to employ less precise, but more congruent, performance measures (e.g., stock price) when contracting with managers who identify little with their organization, while they use more precise but less congruent measures (e.g., accounting earnings) when contracting with managers who identify strongly with the firm. Our theory also predicts that managers who experience critical events that strongly boost their identification with the firm decrease their effort aimed at short-term value creation. Firms optimally react to these large identity shifts by providing steeper incentives while re-balancing relative incentive weights from more congruent but less precise to less congruent but more precise performance measures.

Overall, our model helps explain heterogeneity in performance measurement and incentive contracting within industries as a function of the identity managers take in their firms. More generally, our findings suggest that empirical compensation studies should proxy for a manager's identity to control for endogeneity.

The remainder of the paper is organized as follows: Section II presents the basic single-task, single-performance-measure model to characterize the optimal linear contract and standard that the principal offers to the agent. It demonstrates that contract parameters are not separable from the agent's identity preferences and finally investigates the value of an additional performance measure. Section III analyzes the impact of the agent's identity preferences on optimal incentive rates, effort choice, and the stewardship value of additional performance measures in a multi-task setting. Section IV concludes.

---

[9] In particular, these conditions refer to a setting in which a manager who does not identify with the organization exerts effort beyond the first-best on one task but less than first-best on the other task. In an agency setting, such conditions can arise if the performance measure is non-congruent and the agent is sufficiently risk-tolerant.

II. BASIC MODEL OF IDENTITY PREFERENCES IN A SINGLE-TASK SETTING

Agent's Action, Performance Measure, and Compensation

At date 0, the principal, acting on behalf of the firm's risk-neutral owners, hires an agent to provide personally costly effort $a \in \Re$ at date 1 in return for compensation at date 2. The agent's personal cost of effort is $\kappa(a) = ½\, a^2$. At date 0, the principal also specifies a standard, s, for the agent's effort. We assume that the agent identifies with the organization and thus internalizes the standard such that the agent suffers an additional personal cost if he deviates from the standard:

$$\kappa_s(s,a) = ½\, \gamma(s-a)^2,$$

where $\gamma \geq 0$ scales the loss of identity utility from deviating from the standard. We interpret γ as a measure of the strength with which the agent identifies with the organization.[10] Although violation of the standard is generally not observable by the principal, any deviation causes a personal cost to the agent. For simplicity, we assume that both a positive and a negative deviation from the standard result in a loss of identity utility, which increases with the level of violation.[11]

The agent's identity cost function, $\kappa_s(s, a)$, captures the notion that identity utility depends on the standard of the social reference category. When an agent identifies with an organization, he partly defines himself in terms of the organization and thus is sensitive to the externalities his actions exert on the organization. As a consequence, he perceives a duty to act in accord with the organization's standards and suffers emotional distress if he fails to do so. For such an agent, the standard defines the ideal effort level to serve the organization's best interest. Accordingly, the agent suffers a loss of identity utility because he is either "shirking" when providing effort that falls short of the standard or "ripping off the organization" when providing unnecessary but *costly* effort in excess of the standard. In the first case, the agent feels guilty because he does not contribute as is expected of him. In the second case, the agent feels guilty because he "games" the organization's compensation system by deliberately deviating from the effort the organization wants him to provide to increase his compensation.[12]

At date 2, performance measure y is publicly reported as $y = ma + \varepsilon$, where m is the report's sensitivity to the agent's effort and ε represents uncontrollable events, with $\varepsilon \sim N(0,\sigma^2)$.

---

[10] Throughout the paper, we use the terms "identification with the organization" and "internalization of the standard," interchangeably. Implicitly, our analysis is restricted to a range of standards that the agent perceives to be "reasonable." In our setting, the principal sets the standard equal to the agent's first-best action, which can be regarded as a reasonable standard.

[11] Symmetric loss functions for deviations from standards are also used by Akerlof and Kranton (2005), Brueggen and Moers (2007), Casadesus-Masanell (2004), and Fischer and Huddart (2008). Furthermore, in a single-task setting, the principal will never set a standard below the agent's action, making the assumption of a symmetric loss function innocuous in the single-task setting.

[12] Examples of such reasoning include a surgeon who performs more surgery than necessary in terms of hospital-standards to increase his income, a CEO who accelerates the company's acquisition strategy because his compensation package increases in firm size, or a manager who is compensated based on annual earnings and who increases production without an according increase in sales to shift fixed costs to following periods to increase his current bonus. Aside from higher compensation costs, an agent's deviation from the standard may trigger additional costs for the firm in terms of an increased demand for coordination, slack, or even waste. These additional costs make the assumption about the agent's identity cost function more robust because an agent who identifies with the organization would feel even guiltier when purposely imposing additional costs on the firm with which he identifies. For example, if storing an excessive amount of units causes additional storage costs while increasing annual earnings, a manager feels more guilt about increasing production to boost his compensation. For simplicity, we do not explicitly consider these additional costs.

At date 0, the principal offers the agent a contract, represented by $z = (f,v,s)$, where f is the agent's fixed wage, v is the incentive rate for performance measure y, and s is the standard specified by the principal. Hence, given report y and contract z, the agent's compensation is $w(y,z) = f + vy$.

Agent's Preferences and Action Choice

We assume that the agent has a negative exponential utility function, which is multiplicatively separable in the utility from compensation, u_w, the disutility from effort, u_a, and the distress from not meeting the standard, u_s. Specifically:

$$u(z,a) = u_w(z,a)u_a(a)u_s(s,a) = -\exp[-r\Big(w - \kappa(a) - \kappa_s(s,a)\Big)],$$

where r denotes the agent's coefficient of absolute risk aversion. Maximizing the agent's expected utility is equivalent to maximizing the certainty equivalent, which is characterized by:

$$\begin{aligned} CE(z,a) &= E[w|z,a] - \kappa(a) - \kappa_s(s,a) - ½\, rVar[w|z,a] \\ &= f + v\, ma - ½\, a^2 - ½\, \gamma(s-a)^2 - ½\, rv^2\sigma^2. \end{aligned} \tag{1}$$

Differentiating (1) with respect to a, given contract z, provides the agent's incentive compatibility constraint:

$$vm + \gamma(s - a^\dagger) = a^\dagger, \tag{2}$$

where $a^\dagger$ denotes the action induced by contract z. The benefit to the agent of marginally increasing effort consists of an increase in compensation and, for $s > a$, a reduced identity utility loss because the agent's effort is closer to the standard. Hence, the agent's effort is motivated by monetary incentives, vm, and by identity incentives, $\gamma(s - a)$, which are substitutes with respect to the agent's effort choice. All else equal, Expression (2) implies that as the agent's identification with the organization increases, the standard becomes relatively more important in motivating the agent's effort.

Finally, the agent's individual rationality constraint reflects that he will only participate in the firm if his contract z provides him with his reservation certainty equivalent, which is normalized to zero:

$$CE(z, a^\dagger) \geq 0. \tag{3}$$

Principal's Preferences

We assume that the terminal value of the firm, which is not contractible, is a linear function of the agent's effort, $E[x|a] = ba$, where $b \in \Re$ is the agent's productivity. The expected net terminal value of the firm is:

$$\Pi(z,a) = E[x - w|z,a]. \tag{4}$$

In the first-best case in which the agent's action is contractible, no incentive risk is necessary to induce the agent to undertake a desired action, and it is optimal for the principal to specify first-best effort, $a^* = b$, and to set the standard equal to the first-best effort, $s^* = a^*$. Here, the optimal standard s^* does not depend on the agent's identification with the organization, γ, because the agent implements any action selected by the principal. If the principal sets $s^* = a^*$, then the agent will not suffer a loss of identity utility, implying that the agent's identity preferences are irrelevant.[13]

---

[13] This result indicates that a benefit of our modeling choices is that the first-best expected net profit is not affected by the strength of the agent's identity preferences. Consequently, we can investigate the agency loss for varying degrees of identity without the need to adjust for differences in first-best profits.

Optimal Linear Contract

We now consider the impact of an agent's identity preferences under second best. The principal chooses z to maximize her expected net payoff, (4), subject to the agent's incentive compatibility and individual rationality constraints, (2) and (3). Lemma 1 characterizes the agent's effort choice and the optimal contract offered by the principal.

Lemma 1: The principal's decision problem is separable in the contract's incentive parameters, incentive rate v and standard s. The agent's effort choice, $a^\dagger$, the optimal incentive rate, $v^\dagger$, and the optimal standard, $s^\dagger$, are characterized by (proofs are in Appendix A):

$$a^\dagger(v,s) = \frac{vm + \gamma s}{1+\gamma}, \tag{5a}$$

$$v^\dagger = \frac{bm}{m^2 + r(1+\gamma)\sigma^2}, \text{ and} \tag{5b}$$

$$s^\dagger = b. \tag{5c}$$

Although the optimal incentive rate depends on the agent's internalization of the standard, γ, it is independent of the standard itself (i.e., $\partial v^\dagger/\partial\gamma \neq 0$ and $\partial v^\dagger/\partial s = 0$). From the agent's individual rationality constraint, (3), with an optimal contract, the agent's expected compensation equals the sum of effort costs, identity costs, and risk premium. Substituting the induced action $a^\dagger$, (5a), into the sum of the agent's effort costs, identity costs, and risk premium yields:

$$\kappa(a^\dagger) + \kappa_s(a^\dagger, s) + \tfrac{1}{2} rVar[w|z, a^\dagger] = \tfrac{1}{2}[(1+\gamma)^{-1}m^2 + r\sigma^2]v^2 + \tfrac{1}{2}\gamma(1+\gamma)^{-1}s^2. \tag{6}$$

Expression (6) implies that the marginal cost to the principal of setting incentives via the incentive rate v varies with the agent's identity, γ, but is independent of the standard, s. Intuitively, increasing v yields an effort that is closer to the standard. For $a < s$, this increase in the agent's effort reduces the marginal cost of deviating from the standard, weakening identity incentives. Essentially, weaker identity incentives entail an additional cost to providing monetary incentives. Given a quadratic identity cost function, while this cost increases with the degree γ with which the agent internalizes the standard, it is independent of the action's deviation from the standard.

Lemma 1 also implies that the principal does not adjust the standard based on the strength of the agent's identification with the organization.[14] Consequently, the principal sets the same standard for agents with identical payoff productivity, b, even if the agents differ with respect to their identification with the organization, their risk tolerance, or the characteristics of their performance measures.[15]

---

[14] Following (6), the marginal cost to the principal of setting standard s is $s\gamma(1+\gamma)^{-1}$. Using (5a), the marginal benefit is $b\gamma(1+\gamma)^{-1}$. Equating marginal benefit and marginal cost implies that the optimal standard, $s^\dagger$, is the agent's payoff productivity, b, which equals the agent's first-best action.

[15] In Appendix B we generalize this result by showing that in a multi-task LEN setting with quadratic effort cost and identity cost functions, the optimal standards are the agent's first-best actions. Intuitively, the marginal cost to the principal of setting the standards continues to be independent from the marginal cost of providing monetary incentives. Importantly, this result is independent of the number and properties of contractible performance measures available to the principal. While we can show that all of our main results hold with an identity cost function that increases linearly in the deviation from the standard, the result of a constant standard stems from the quadratic identity cost function. The latter analysis is available from the authors upon request.

The above discussion assumes that the principal sets a standard that exceeds the agent's effort. Proposition 1 next shows that this assumption is without loss of generality.

Proposition 1: In a single-task agency setting:

(i) the principal chooses a standard that exceeds the agent's effort (i.e., $s^{\dagger} > a^{\dagger}$);
(ii) an agent who fully identifies with the firm supplies first-best effort (i.e., $\lim_{\gamma \to \infty} a^{\dagger} = b$);
(iii) an agent's effort increases in his identity (i.e., $\partial a^{\dagger}/\partial \gamma > 0$); and
(iv) identity incentives and monetary incentives are substitutes (i.e., $\partial v^{\dagger}/\partial \gamma < 0$).

Proposition 1(i) in conjunction with $s^{\dagger} = b$ illustrates that identity incentives are generally not sufficient to achieve first-best because the moral hazard problem is not resolved when the agent suffers a loss of identity utility when deviating from a standard. This implies that the principal sets a standard from which the agent will surely deviate, i.e., the principal offers a contract that imposes identity costs on the agent.

When setting the standard, the principal trades off the identity costs and the benefits of identity incentives that motivate the agent to supply more effort.[16] Part (ii) of Proposition 1 shows that if the agent fully identifies with the firm, $\gamma \to \infty$, then he chooses the first-best action and thus suffers no identity costs.

By setting $s^{\dagger} > a^{\dagger}$, the principal imposes identity costs on the agent, which increase in the agent's desire to meet the standard. To avoid a loss of identity utility, the agent works harder. In turn, the principal reduces monetary incentives because the induced identity incentives more than compensate for the reduction in monetary incentives. This result confirms the finding of prior literature that the principal reduces incentives when contracting with an agent who strongly identifies with the firm (Akerlof and Kranton 2005).

Finally, the principal's expected net profit in the second-best case is given by:

$$\Pi^{\dagger}(\eta_1) = ½ \frac{\gamma}{1+\gamma} b^2 + ½ \frac{1}{1+\gamma} \cdot \frac{b^2 m^2}{m^2 + r(1+\gamma)\sigma^2}, \tag{7}$$

where η_1 indicates an information system that generates a single performance measure, y. Using (7), it is straightforward to show that the principal benefits from contracting with an agent who identifies with the organization and that the benefit increases in the agent's identity, γ. However, except in the knife-edge case where the agent fully identifies with the firm, $\gamma \to \infty$, the principal cannot achieve first-best. Therefore, the principal may want to reduce agency costs by contracting on multiple performance measures.

Stewardship Value of Additional Performance Measures

In many organizations, a principal has access to multiple performance measures. Earlier agency literature has provided extensive characterizations of the relative incentive weights for these measures and the stewardship value of additional performance measures (Lambert 2001). We next study how these characterizations change when the agent has identity preferences.

We extend the previous model by assuming that the principal may contract on a second signal, y_e, that reports on uncontrollable events affecting signal y. More specifically, information system η_2

---

[16] This result is similar to the argument that, in an adverse-selection setting, distorted performance measures may be beneficial to the principal. Following Maggi and Rodríguez-Clare (1995), given a convex cost of distortion, motivating distortion in equilibrium results in a higher marginal cost of distortion, which may provide a countervailing incentive that eases an agent's self selection. We thank Brian Mittendorf for pointing out this connection.

generates two signals, y and y_e, with $y = ma + \varepsilon$, $\varepsilon \sim N(0,\sigma^2)$, $y_e = \varepsilon_e$, $\varepsilon_e \sim N(0,\sigma_e^2)$, and $\mathrm{Cov}[y,y_e] = \rho\sigma\sigma_e$.[17] The agent's compensation is given by $w = f + vy + v_e y_e$. Lemma 2 summarizes the optimal incentive rates and the principal's expected net payoff.

> **Lemma 2:** Consider a single-task agency setting with two performance measures, y and y_e. The optimal incentive rates and the principal's expected net payoff become:

$$v^\dagger = \frac{bm}{m^2 + r(1+\gamma)(1-\rho^2)\sigma^2}, \tag{8a}$$

$$v_e^\dagger = -\rho\frac{\sigma}{\sigma_e}v^\dagger, \text{ and} \tag{8b}$$

$$\Pi^\dagger(\eta_2) = ½\frac{\gamma}{1+\gamma}b^2 + ½\frac{1}{1+\gamma}\cdot\frac{b^2m^2}{m^2 + r(1+\gamma)(1-\rho^2)\sigma^2}. \tag{8c}$$

Here the optimal standard is independent of the monetary incentives and hence is set to equal the first-best effort. By comparing the agent's performance in y with the one in y_e, the principal can filter out the impact of uncontrollable events on the agent's compensation (Antle and Demski 1988). Following (8a) and (8b), the agent's identity preferences affect the two incentive rates $v^\dagger$ and $v_e^\dagger$, such that both incentive rates decrease in the agent's identity, γ. Given that identity incentives substitute for monetary incentives, the incentive risk imposed on the agent via $v^\dagger$ decreases with γ. Consequently, less filtering via $v_e^\dagger$ is required for a stronger identification with the organization.

We define the value of an additional performance measure as the difference in expected net payoff to the principal with and without this measure. Specifically, given information system η_1 with a single performance measure, y, and information system η_2 with signals y and y_e, using (7) and (8c) the value of y_e becomes:

$$V^\dagger = \Pi^\dagger(\eta_2) - \Pi^\dagger(\eta_1) = ½\frac{b^2m^2r\rho^2\sigma^2}{(m^2 + r(1+\gamma)\sigma^2)(m^2 + r(1+\gamma)(1-\rho^2)\sigma^2)}. \tag{9}$$

Proposition 2 summarizes the consequences of varying strength of the agent's identity on the optimal incentive ratio, $IR^\dagger = v_e^\dagger / v^\dagger$, and the value of an additional performance measure, $V^\dagger$.

> **Proposition 2:** Consider a single-task agency setting with two performance measures:
>
> (i) the ratio of the two incentive rates is independent of the agent's identity (i.e., $\partial IR^\dagger/\partial\gamma = 0$); and
>
> (ii) the value of an additional performance measure is decreasing in the agent's identity (i.e., $\partial V^\dagger/\partial\gamma < 0$).

Proposition 2(i) implies that both incentive rates decrease at the same rate when the agent identifies more strongly with the organization. The key to this result is that optimal risk filtering via $v_e^\dagger$ is directly proportional to the risk imposed on the agent via $v^\dagger$ from (8b). Hence, while the relevance of monetary incentives declines with an agent's identification with the organization, the relative importance of an additional signal on uncontrollable events is independent of the agent's identity.

---

[17] Note that assuming y_e is not action-informative, $\partial E[y_e]/\partial a = 0$, is without loss of generality. We can always transform any signal y_a with $\partial E[y_a]/\partial a \neq 0$, into y_a', where $\partial E[y_a']/\partial a = 0$, such that (y,y_a') is an equivalent statistic for (y,y_a).

By filtering out the impact of uncontrollable events on an agent's compensation, the principal reduces the agent's risk premium. Consequently, stronger monetary incentives are more attractive to the principal. On the other hand, a stronger identification with the organization entails weaker monetary incentives, which reduces the value of an additional signal that can be used to filter out the impact of uncontrollable events.

For the single-task setting, our result matches the common intuition that identity incentives and monetary incentives are substitutes. Moreover, while the relative incentive weights placed on the measures are unaffected by an agent's perceived pressure to meet the standard, the value of an additional performance measure decreases with an agent's identity. Regarding the design of performance measurement systems, the latter results suggest that empirical studies on the relative importance of performance signals for incentive purposes do not need to control for an agent's identity when the set of measures is held constant. However, the set of performance measures decreases in an agent's identity, suggesting that neglecting an agent's identity in empirical studies introduces the possibility of correlated omitted variables.

III. IDENTITY PREFERENCES IN A MULTI-TASK SETTING

In this section, we extend our initial analysis to a multi-task setting. In multi-task agency settings, performance measure noncongruity introduces an additional efficiency loss to the principal (Feltham and Xie 1994). Accordingly, in this section, we explore the impact of an agent's identity on the interrelation between monetary incentives and performance measurement when an agent is responsible for multiple tasks with a single performance measure and multiple performance measures.

Two-Task Setting with a Single Performance Measure

Optimal Linear Contract

The impact of an agent's identity preferences becomes more subtle if the agent is responsible for multiple tasks. The agent now controls two tasks, a_1 and a_2, at cost $\kappa(a_1,a_2) = ½(a_1{}^2 + a_2{}^2)$. The expected gross value of the firm is represented by $E[x|a_1,a_2] = b_1a_1 + b_2a_2$. As in the previous section, we initially consider an information system, η_1, that generates a single performance measure, $y = m_1a_1 + m_2a_2 + \varepsilon$, with $\varepsilon \sim N(0, \sigma^2)$.

The principal specifies a standard, s_i, for each action a_i, $i = 1,2$. To keep the analysis simple while retaining the same model structure, we assume that the agent's disutility of deviating from the standards is homogeneous, such that the agent has no direct preference for a specific standard, and separable, such that compliance with one standard does not affect the cost of deviating from the other standard:

$$\kappa_s(s_1, s_2, a_1, a_2) = ½\gamma\left\{(s_1 - a_1)^2 + (s_2 - a_2)^2\right\}.$$

Using this parametrization, Lemma 3 characterizes the optimal contract and the principal's net payoff.

Lemma 3: Given a two-task agency setting with a single performance measure, the optimal standards, incentive rate, and the principal's expected net payoff become:

$$s_1^\dagger = b_1 \text{ and } s_2^\dagger = b_2, \tag{10a}$$

$$v^{\dagger} = \frac{b_1 m_1 + b_2 m_2}{m_1^2 + m_2^2 + r(1+\gamma)\sigma^2}, \text{ and} \tag{10b}$$

$$\Pi^{\dagger}(\eta_1) = \frac{1}{2}\frac{\gamma}{1+\gamma}(b_1^2 + b_2^2) + \frac{1}{2}\frac{1}{1+\gamma} \cdot \frac{(b_1 m_1 + b_2 m_2)^2}{m_1^2 + m_2^2 + r(1+\gamma)\sigma^2}. \tag{10c}$$

Several insights from the single-task setting regarding the impact of identity preferences remain valid for the two-task setting. For example, the standards are set equal to the first-best action, the incentive rate decreases with an agent's identification with the organization, γ, and the principal's expected net payoff increases with γ. However, while an agent's effort increases with γ in the single-task setting, the relation is more subtle in a multi-task setting.

Identity Preferences and Induced Effort

To understand the consequences of an agent's identity preferences in a multi-task setting, we first analyze the relative effort levels that can be induced by the principal. If there are two tasks, then the first-best effort ratio is $ER^* = a_1^*/a_2^* = b_1/b_2$. Under second best, the agent's effort allocation is characterized by:

$$ER^{\dagger}(v, s_1, s_2) = \frac{a_1^{\dagger}(v, s_1)}{a_2^{\dagger}(v, s_2)} = \frac{m_1 v + \gamma s_1}{m_2 v + \gamma s_2}. \tag{11}$$

When the agent does not identify with the organization, $\gamma = 0$, the effort ratio reflects the signal's sensitivity to the agent's actions (i.e., $ER^{\dagger} = m_1/m_2$ if $\gamma = 0$). Thus, the performance measure limits the inducible effort ratio such that a congruent performance measure, $m_1/m_2 = b_1/b_2$, is a necessary and sufficient condition for the principal to implement the first-best effort ratio. In contrast, when the agent identifies with the organization, $\gamma > 0$, the principal can induce any pair of actions. However, by setting optimal standards the principal does not, in general, induce the first-best effort ratio.[18] Specifically, using (10a) and (10b) in (11), the principal chooses to implement an effort ratio $ER^{\dagger}$ that reflects the agent's identity as well as the agent's risk aversion, the noisiness of the performance measure, and the agent's payoff productivity in both tasks. With a noncongruent performance measure, $m_1/m_2 \neq b_1/b_2$, identity incentives and monetary incentives induce divergent effort allocations. While identity incentives induce a first-best effort allocation such that $ER^{\dagger} = s_1^{\dagger}/s_2^{\dagger} = b_1/b_2$ if $v = 0$, monetary incentives induce an effort allocation along the sensitivity of the performance measure (i.e., $ER^{\dagger} = m_1/m_2$ if $\gamma = 0$), and the relative strength of monetary incentives varies with the incentive rate from (10b).

Considering the influence of identity preferences on an agent's effort in a multi-task setting, similar to the single-task setting, the agent's effort in each task is driven by identity and monetary incentives. While identity incentives increase in an agent's identity, monetary incentives decrease in γ. In a single-task setting, the first effect dominates, implying that an agent's effort increases with γ. Proposition 3 illustrates that the relation is more subtle in a multi-task setting.[19]

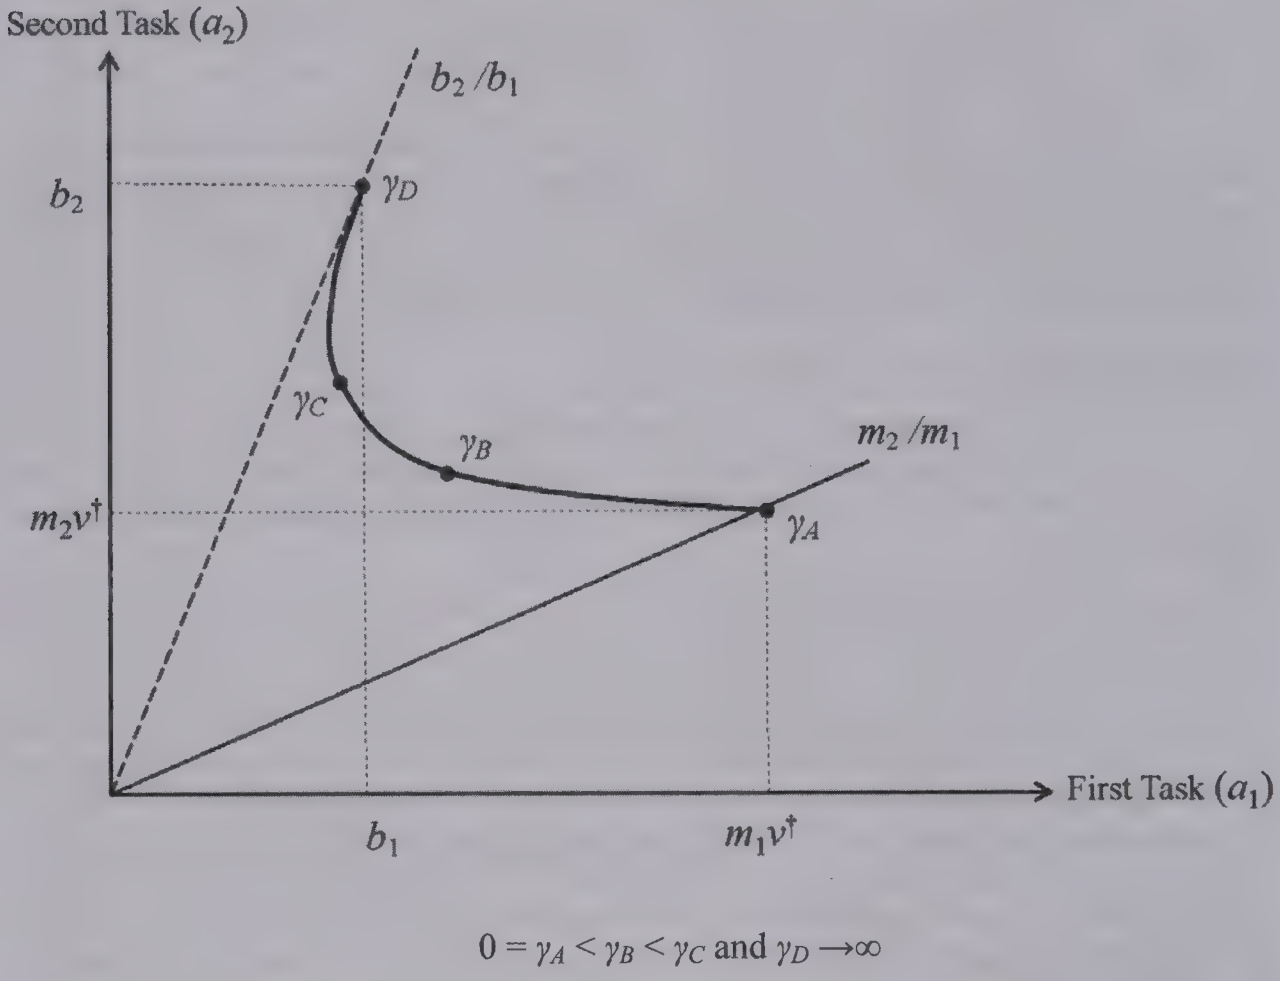
Proposition 3: In a two-task agency setting, the impact of an agent's identity on the effort induced by the principal is ambiguous. Necessary and sufficient conditions for a negative impact of identity on the effort for task i are:

---

[18] The first-best effort ratio is achieved only for knife-edge cases where the performance measure is congruent with the principal's payoff, the principal does not offer monetary incentives, or the agent fully identifies with the organization.

[19] For expositional brevity, we characterize all cutoff values, such as r_c and γ_c in the respective proofs.

FIGURE 1
Impact of an Agent's Identity on his Effort Allocation



(i) the performance measure places a relatively larger weight on task i as compared with task l (i.e., $m_i/m_l > b_i/b_l$, $i, l = 1,2$ and $i \neq l$);
(ii) the agent is sufficiently risk tolerant (i.e., $r < r_c$); and
(iii) the agent only weakly identifies with the firm (i.e., $\gamma < \gamma_c$).

Proposition 3 is illustrated in Figure 1. The solid line depicts the agent's effort allocation for varying degrees of identity, with γ increasing from γ_A to γ_D. Intuitively, under the conditions outlined in Proposition 3(i) and (ii), the second-best effort exceeds the first-best effort for one of the agent's tasks. In Figure 1, at γ_A, while the agent's effort in task 2 is below the standard $s_2^\dagger$ (i.e., $a_2^\dagger < b_2$ if $\gamma = 0$), the effort in task 1 exceeds the standard $s_1^\dagger$ (i.e., $a_1^\dagger > b_1$ if $\gamma = 0$). Applying the logic of Proposition 1(ii) to a multi-task setting, the agent supplies first-best effort if he fully identifies with the firm (i.e., $a_i^\dagger = b_i$ at $\gamma_D \to \infty$, $i = 1,2$). For a stronger identity, e.g., when increasing γ from γ_B to γ_C, the agent's effort allocation "moves closer" to first-best. Then, following the intermediate value theorem, the effort in one task necessarily decreases in the agent's identity.

A negative impact of identity on effort can also apply in settings where the agent's effort in his multiple tasks is below the standards, but the effort allocation is skewed toward one of the tasks.

Such a situation is depicted at γ_C, where $a_1^{\dagger} < b_1$ but, at the same time, $\partial a_1^{\dagger}/\partial\gamma < 0$. Recall that identity incentives increase in an agent's identity and the principal optimally reduces monetary incentives for higher γ. If the agent's risk aversion is neither too low nor too high, then this reduction of monetary incentives can dominate the increase in identity incentives.[20]

To summarize, in a multi-task setting, the impact of an agent's identity on effort is ambiguous. If effort is very hard to motivate with actions well below the standards, then an agent's effort in each task increases in his identity. Otherwise, the relation between an agent's effort and his identification with the organization can be U-shaped such that the effort first decreases in the agent's identity but then increases once the identity is sufficiently strong.

Our findings have interesting implications for an organization that ties incentive compensation to a single performance measure such as accounting earnings. If the measure is inherently noncongruent and does not reflect a manager's contribution to firm value adequately, a firm risks inducing an unbalanced allocation of effort across tasks. For example, activities aimed at increasing short-term value are generally assumed to be better reflected in performance measures than those aimed at increasing long-term value (Horngren et al. 2010; Ittner and Larcker 2003).[21] Recently, identity initiatives that foster employees' identification with their organization have been suggested as a remedy to the effort-allocation problem (Alvesson and Robertson 2006; Alvesson and Willmott 2002; Ravasi and Phillips 2011). Our model predicts that successfully implemented identity initiatives in firms that inspired a low identification before the initiative can undermine (boost) managers' effort in short-term (long-term) value generation. As a consequence, when short-term performance is critical to firm survival, e.g., due to short-term liquidity issues, this effect may constitute an important boundary condition to fostering identification in practice.

Accordingly, our model suggests that over the short run, a firm's performance measures may provide contrarian signals about the economic success of an identity initiative. This can trigger nontrivial costs for the firm if analysts and investors misinterpret a reduction in short-term performance as an indication that the initiative was not successful or even detrimental to firm value. Thus, our model also highlights the potential for the performance measurement system to reflect the economic success of identity initiatives only after a significant time lag.

Our theory further predicts that events that strongly weaken the identification with the firm,[22] can boost (undermine) employees' effort for tasks that are well (not well) reflected in the firm's performance measurement system. For example, after a merger employees of an acquired firm often identify less with their new organization than the employees of the acquirer (Giessner et al. 2011; Ullrich and van Dick 2007). Here our theory predicts that employees of the acquired firm will exert more effort on tasks that the new organization's performance measurement system measures well and provide less effort on tasks that are hard to measure relative to employees of the acquiree. Consequently, after a merger, employees of an acquired firm tend to engage more in short-term than in long-term value generation. More generally, our model predicts cross-sectional variation across firms with respect to the effort that managers exert on short-term versus long-term value creation as a function of their identification with the organization.

---

[20] More precisely, $\exists\, r \in (r_u, r_c)$, where r_u yields $a_i^{\dagger}|_{\gamma=0} = b_i$, $i = \{i | m_i/m_l > b_i/b_l,\ i, l = 1,2 \text{ and } i \neq l\}$, and r_c is given in the proof to Proposition 3, such that $a_i^{\dagger} < b_i$ and $\partial a_i^{\dagger}/\partial\gamma < 0$ for γ is sufficiently small. This result shows that our assumption of an identity cost function where the agent experiences distress when he supplies effort above the standard is not a necessary condition for the ambiguous impact of identity on effort.

[21] In our model, one could think of a_1 as reflecting short-term effort and a_2 as reflecting long-term effort. Consequently, short-term effort being better reflected in the performance measure implies $m_1/m_2 > b_1/b_2$.

[22] Such events could include fear of downsizing, dim career perspectives, corporate restructuring, mergers and takeovers, strategic change, or continuing losses (Petriglieri 2011; Terry et al. 2001; Ullrich and van Dick 2007).

Identity Preferences and Performance Measure Choice

In this subsection, we consider the impact of identity preferences on the relative importance of precision and congruity, two key indicators of the contracting usefulness of performance measures. For the two-task setting, the expected net payoff to the principal under second best is given by (10c), and the first-best expected net payoff is $\Pi^* = ½(b_1{}^2 + b_2{}^2)$. Therefore, the loss of surplus to the principal is:

$$L = \Pi^* - \Pi^\dagger = ½\frac{\dfrac{(b_2m_1 - b_1m_2)^2}{(1+\gamma)} + r(b_1^2 + b_2^2)\sigma^2}{m_1^2 + m_2^2 + r(1+\gamma)\sigma^2}. \tag{12}$$

According to Feltham and Xie (1994), $(b_2m_1 - b_1m_2)^2$ reflects the loss due to performance measure noncongruity, while the second term in the numerator of (12) reflects the loss due to performance measure noise. The total loss of surplus decreases in an agent's identity, γ. More importantly, Expression (12) suggests that γ affects the relative size of the two types of losses, in turn affecting the relative importance of performance measure congruity and precision for the solution of the agency conflict.

Proposition 4: In a two-task agency setting with a single performance measure, the loss due to noncongruity relative to the loss due to performance measure noise decreases with an agent's identification with the organization.

Key to Proposition 4 is that identity incentives induce the first-best effort allocation and substitute for monetary incentives. Thus, the second-best effort allocation induced by a noncongruent performance measure becomes less relevant for total effort allocation when an agent more strongly identifies with the organization.

Proposition 4 shows that identity preferences affect a principal's choice among performance measures. To illustrate this impact, consider a setting in which the principal may choose between two information systems, $\eta_1{}'$ and $\eta_1{}''$. While $\eta_1{}'$ discloses a congruent report $y_1{}'$, signal $y_1{}''$ of $\eta_1{}''$ is noncongruent but more precise. Specifically, $y_1{}' = b_1a_1 + b_2a_2 + \varepsilon_1$, with $\varepsilon_1 \sim N(0,\sigma_1{}^2)$, and $y_2{}'' = m_1a_1 + m_2a_2 + \varepsilon_2$, with $\varepsilon_2 \sim N(0,1)$, $\mathrm{Var}[y_1{}'] = \sigma_1{}^2 > \mathrm{Var}[y_1{}''] = 1$, and $m_1/m_2 \neq b_1/b_2$.

Using this parametrization in (10c) yields the principal's expected net payoffs $\Pi^\dagger(\eta_1{}')$ and $\Pi^\dagger(\eta_1{}'')$. The principal strictly prefers $\eta_1{}'$ over $\eta_1{}''$ if $\Pi^\dagger(\eta_1{}') > \Pi^\dagger(\eta_1{}'')$. This condition is equivalent to:

$$\sigma_1^2 < \sigma_c^2 \equiv \frac{(b_1^2 + b_2^2)\left((b_1m_2 - b_2m_1)^2 + r(1+\gamma)(b_1^2 + b_2^2)\right)}{r(1+\gamma)(b_1m_1 + b_2m_2)^2}, \tag{13}$$

where $\sigma_c{}^2$ equates $\Pi^\dagger(\eta_1{}')$ and $\Pi^\dagger(\eta_1{}'')$. Intuitively, the principal prefers the congruent system, $\eta_1{}'$, over the noncongruent system, $\eta_1{}''$, if the congruent measure is not too noisy. From (13), the precision of y_1 that is necessary for the principal to prefer $\eta_1{}'$ over $\eta_1{}''$ increases with an agent's identity (i.e., $\partial\sigma_c{}^2/\partial\gamma < 0$).

This section shows that, when organizations employ a single performance measure, the more employees identify with the firm, the less important is the measure's congruity relative to its precision. Therefore, our model predicts that firms are more likely to employ less precise but more congruent performance measures, such as stock prices, when contracting with managers who identify very little with their organization, while they will use more precise but less congruent measures, such as accounting earnings, when contracting with managers who strongly identify with their firm. This prediction is in accord with insights about incentive contracts of newly appointed CEOs who were either promoted from inside or hired from outside the firm (Bouwens and Kroos

2010). We would argue that managers who are promoted from the inside identify more strongly with the firm than managers who are hired from the outside.[23] As a consequence, it seems important to provide newly hired CEOs from the outside with congruent incentives, even if those incentives may rely on relatively noisy measures. In line with our predictions, Bouwens and Kroos (2010) find that incentives for new "outside" CEOs are based less on accounting earnings and more on stock market returns when compared with incentives for CEOs who were promoted from inside the firm.

Additional Performance Measures in a Multi-Task Setting

Optimal Linear Contract

To demonstrate how identity preferences affect the relative weights placed on performance measures and the value of additional performance measures in a multi-task setting, we extend the previous analysis by assuming that information system η_2 generates two performance measures, y and y_a. While y is an aggregate measure of the agent's effort in each task, a_1 and a_2, assume that y_a only captures effort for task a_1. Specifically, $y = m_1 a_1 + m_2 a_2 + \varepsilon$, $y_a = m_a a_1 + \varepsilon_a$, $\varepsilon \sim N(0,\sigma^2)$, $\varepsilon_a \sim N(0,{\sigma_a}^2)$, and $\mathrm{Cov}[\varepsilon,\varepsilon_a] = 0$. With η_2, the agent's compensation is given by $w = f + vy + v_a y_a$.

Using this parametrization, Lemma 4 characterizes the optimal contract and the principal's net payoff.

Lemma 4: In a two-task agency setting with two performance measures, y and y_a, the optimal standards, incentive rates, and the principal's expected net payoff become:

$$s_1^\dagger = b_1, \text{ and } s_2^\dagger = b_2, \tag{14a}$$

$$v^\dagger = D^{-1}\left[\left(m_a^2 + r(1+\gamma)\sigma_a^2\right)(b_1 m_1 + b_2 m_2) - b_1 m_1 m_a^2\right], \tag{14b}$$

$$v_a^\dagger = D^{-1}\left[-m_1 m_a (b_1 m_1 + b_2 m_2) + \left(m_1^2 + m_2^2 + r(1+\gamma)\sigma^2\right) b_1 m_a\right], \text{ and} \tag{14c}$$

$$\begin{aligned}\Pi^\dagger(\eta_2) &= ½\frac{\gamma}{1+\gamma}(b_1^2 + b_2^2) \\ &\quad + ½\frac{1}{1+\gamma} D^{-1}\left[(b_1^2 + b_2^2) m_2^2 m_a^2 + r(1+\gamma)\left(b_1^2 m_a^2 \sigma^2 + (b_1 m_1 + b_2 m_2)^2 \sigma_a^2\right)\right],\end{aligned} \tag{14d}$$

where:

$$D = \left(m_1^2 + m_2^2 + r(1+\gamma)\sigma^2\right)\left(m_a^2 + r(1+\gamma)\sigma_a^2\right) - m_1^2 m_a^2.$$

Recall that, in a single-task setting, the incentive weight assigned to either a single or multiple performance measures decreases with an agent's identity, γ. Likewise, in a multi-task setting, the incentive weight for a single performance measure decreases with γ. To the contrary, in a multi-task setting with multiple performance measures, the impact of an agent's identity on the incentive rates is more subtle. Moreover, while the ratio of incentive rates, $IR^\dagger = v^\dagger / {v_a}^\dagger$, is independent of an agent's identity in a single-task setting, it varies in a nontrivial way with γ in a multi-task setting.

Proposition 5: In a two-task agency setting with two performance measures, y and y_a:

---

[23] See also Boivie et al. (2011) for a similar argument.

(i) the impact of an agent's identity on the incentive rates is ambiguous. Specifically, when an agent weakly identifies with the firm, the incentive rates increase in an agent's identity (i.e., $\partial v^{\dagger}/\partial\gamma > 0$ for $\gamma < \gamma'$ and $\partial v_a{}^{\dagger}/\partial\gamma > 0$ for $\gamma < \gamma''$); and

(ii) for an increasing identity, the principal assigns a relatively larger weight on performance measure y_a as compared with measure y if the latter is biased toward measuring task 1 (i.e., $\partial IR^{\dagger}/\partial\gamma < 0$ if $m_1/m_2 > b_1/b_2$).

Proposition 5 demonstrates how the triangular relation between managerial identity, performance measure congruity, and the principal's calibration of incentive rates to managerial identity and performance-measure congruity influences an agent's effort choice. The ambiguous impact of identity preferences on monetary incentives is driven by two disparate, though intertwined, effects. First, absent identity preferences, noncongruent performance measures impose a discount on incentives and thus tend to flatten incentives as compared with more congruent performance measures (Feltham and Xie 1994). Second, stronger identity preferences tend to reduce the bias imposed by noncongruent performance measures such that, for a given level of monetary incentives, stronger identity preferences reduce the "noncongruity discount" on monetary incentives. The reduced discount can make the use of stronger monetary incentives more attractive for the principal. Therefore, to improve a manager's effort allocation over multiple tasks, the principal will offer stronger incentives to managers who partially identify with the organization.

While the impact of an agent's identity on the incentive ratio is generally ambiguous, Proposition 5(ii) characterizes conditions where the principal assigns, for increasing γ, a relatively larger weight on y_a as compared with y. In a multi-task setting with non-aligned performance measures, varying the incentive ratio induces a variation in the agent's effort allocation. Specifically, for the conditions characterized in Proposition 5(ii), the principal places a relatively larger weight on performance measure y_a, which captures task 1, even though performance measure y is (also) biased toward measuring task 1. Again, the intuition for this result follows from the impact of identity preferences on the noncongruity discount on incentives.

The results of this section indicate that, when firms use multiple performance measures for incentive compensation, the level of a manager's identification with the firm influences both the absolute intensity of the manager's incentives and the relative incentive weights assigned to the different measures.[24] Employing a mix of performance indicators inevitably involves the use of some measures that are more congruent than others. Our model provides insight concerning how to choose the optimal intensity of the manager's incentives and how to re-balance the incentive weights assigned to more or less congruent performance measures as a function of the manager's identification with the firm. For example, many firms base their incentive compensation on some mix of stock price and accounting earnings. Our model predicts that the more managers identify with their organization, the more firms will put a higher weight on accounting earnings *vis-à-vis* stock prices in managers' incentives. Furthermore, we expect identity initiatives in low-identification firms to be associated with steeper incentives and a re-balancing of incentive weights from stock price to accounting earnings.

Stewardship Value of Additional Performance Measures

The expected net payoff to the principal increases as agents identify more strongly with the firm. In a single-task setting, the increase in net payoff with an information system that generates a single performance measure is larger than the increase with an information system that generates two performance measures. Consequently, the stewardship value of an additional performance measure decreases with an agent's identity, implying that a principal will use fewer performance measures when contracting with an agent who identifies more strongly with the firm.

---

[24] More generally, our study suggests that incentive weights on performance measures vary non-trivially with a manager's "pro-social" or "other regarding preferences." Relatedly, Bouwens and van Lent (2010) find that a measure of group conformity asymmetrically influences the incentive weights on financial and nonfinancial measures of performance.

In a multi-task setting, given that information system η_1 generates y and information system η_2 generates y and y_a, using (10c) and (14d), the value of y_a, $V^\dagger = \Pi^\dagger(\eta_2) - \Pi^\dagger(\eta_1)$, is characterized by:

$$V^\dagger = ½(1+\gamma)^{-1}\left(m_1^2 + m_2^2 + r(1+\gamma)\sigma^2\right)^{-1} D^{-1}[m_2(b_1 m_2 - b_2 m_1) - r(1+\gamma)\sigma^2 b_1]^2 m_a^2. \tag{15}$$

Proposition 6 shows that, in a multi-task setting, the value of an additional performance measure does not necessarily decrease in how strongly the agent identifies with the firm, suggesting an overall ambiguous relation between the number of signals used for performance evaluation and an agent's identification with the firm.

Proposition 6: In a two-task agency setting with two performance measures, y and y_a, the impact of an agent's identification with the firm on the value of an additional signal, y_a, is, in general, ambiguous.

(i) For a risk-neutral agent, the value of an additional performance measure decreases with the agent's identity (i.e., $\partial V^\dagger/\partial\gamma < 0$ if $r \rightarrow 0$);
(ii) For an extremely risk-averse agent, the value of an additional performance measure is unaffected by the agent's identity (i.e., $\partial V^\dagger/\partial\gamma = 0$ if $r \rightarrow \infty$); and
(iii) A sufficient condition for a positive impact of an agent's identity on the value of an additional performance measure is that the initial performance measure, y, is sufficiently misaligned (i.e., $m_1/m_2 - b_1/b_2$ is sufficiently positive).

The key to Proposition 6(i) is that the principal can use the two performance measures generated by η_2 to construct an "overall" performance measure, which is congruent with her expected payoff. Agent risk-neutrality implies that, despite the noisiness of this constructed performance measure, the principal can still achieve first-best. Since $\Pi^\dagger(\eta_1)$ increases in γ, $V^\dagger$ decreases in the agent's identity. Intuitively, for a risk-neutral agent, efficiency losses relate only to performance measure noncongruity, and the relevance of this efficiency loss decreases with γ. On the other hand, for an extremely risk-averse agent, the principal refrains from offering monetary incentives. Under η_1 and η_2, the agent's effort is driven only by identity incentives, implying that the value of generating an additional performance measure is zero.

Proposition 6(i) and (ii) suggest that the value of an additional performance measure, $V^\dagger$, may increase in an agent's identity only for a sufficient risk tolerance (i.e., $\partial V^\dagger/\partial\gamma > 0$ only if $r \in (0, r_{max})$). Proposition 6(iii) states a sufficient condition for a positive impact of γ on $V^\dagger$ that complements the necessary condition on the risk tolerance.[25]

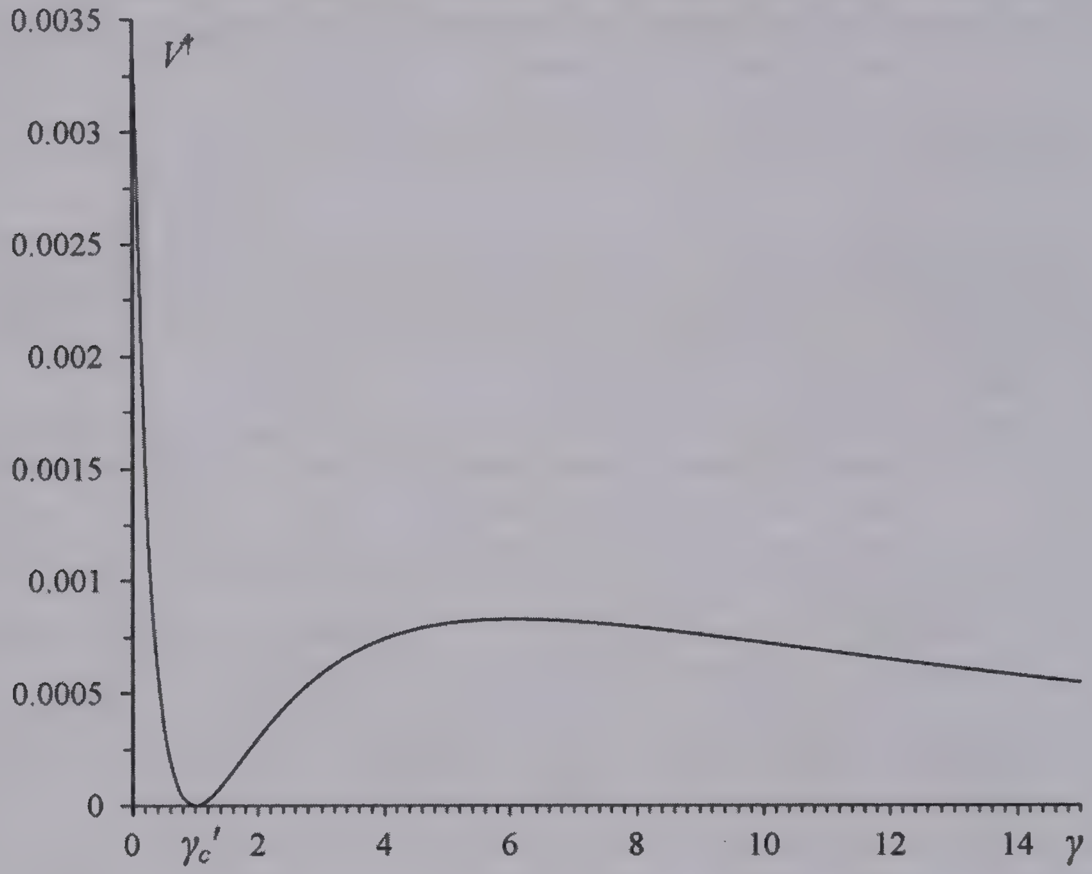
The key to Proposition 6(iii) is that the principal trades off marginal costs and benefits from contracting on the additional measure y_a. Assuming that the initial performance measure y is biased toward task 1, $m_1/m_2 > b_1/b_2$, a positive incentive weight on y_a increases the incentives for the agent to deviate further from the first-best effort allocation as it shifts the incentives toward task 1. However, as the two performance measures are not correlated, an increase in v_a enables the principal to decrease v and thus reduce the risk imposed on the agent. In turn, a negative incentive weight on y_a has the opposite effect, because it partly removes the incongruence associated with the initial measure. This allows the principal to increase v accordingly, thereby increasing the risk

---

[25] While the necessary condition of intermediate levels of risk tolerance is straightforward from Proposition 6(i) and (ii), characterizing this interval requires solving a fourth-order polynomial.

FIGURE 2

Impact of the Agent's Internalization of the Standard, γ, on the Value $V^{\dagger}$ of Generating an Additional Performance Measure in a Two-Task Setting



imposed on the agent. While the principal faces a trade-off between noncongruence and imposed risk even in the absence of identity preferences, the analysis in the section "Identity Preferences and Performance Measure Choice" indicates that, the stronger the agent's identity, the less important is the congruity of a performance measure to evaluate the agent. Thus, when the initial measure is biased toward task 1 and the agent is sufficiently risk-tolerant, absent identity preferences, the principal chooses $v_a^{\dagger} < 0$ to reduce the noncongruence associated with the initial performance measure. As γ increases, reducing the noncongruence becomes less important such that $v_a^{\dagger}$ approaches zero and, for some γ, the principal will choose $v_a^{\dagger} = 0$.[26] If γ increases further, then the noncongruence induced by monetary incentives becomes less consequential such that the principal uses the additional measure to reduce the induced risk imposed on the agent by setting $v_a^{\dagger} > 0$ while also reducing $v^{\dagger}$. Importantly, $V^{\dagger} = 0$ if $v_a^{\dagger} = 0$, implying an ambiguous relation between $V^{\dagger}$ and γ.

Figure 2 illustrates Proposition 6(iii) for parameter values $b_1 = b_2 = 1$, $m_1 = 3$, $m_2 = m_a = 1$, $r = 1$, and $\sigma = \sigma_a = 1$. Following (14c), $v_a^{\dagger} = 0$ for $\gamma = \gamma_c' = (m_2/b_1)(b_2 m_1 - b_1 m_2)/(r\sigma^2) - 1$, implying that $V^{\dagger} = 0$ if $\gamma = \gamma_c'$. For $\gamma < \gamma_c'$, the principal selects $v_a^{\dagger} < 0$ to construct an overall performance measure that is more congruent with her payoff. Here, the value of an additional measure decreases in γ because identity preferences reduce the need for the principal to construct a more congruent overall performance measure. For $\gamma > \gamma_c'$, the principal selects $v_a^\dagger > 0$. While this yields an overall performance measure that is even less congruent with her payoff than y, the relatively strong identity incentives impair the agent's monetary incentives to select an effort allocation that differs substantially from first-best. In turn, choosing a positive incentive rate $v_a^\dagger$ enables the principal to reduce the incentive rate $v^\dagger$ for performance measure y, resulting in a beneficial reduction of the agent's risk premium. Finally, for sufficiently high γ (for $\gamma > 6.04$ in the example), identity incentives dominate the agent's action choice, monetary incentives are relatively less important, and the value of an additional performance measure decreases in the agent's identity.

---

[26] More generally, using (14c), the principal chooses $v_a^{\dagger} = 0$ if $-r\sigma^2 + m_2/b_1(1+\gamma)^{-1}(b_2 m_1 - b_1 m_2) = 0$, where the first term reflects the marginal cost from changing the agent's risk premium and the second term reflects the marginal benefit from reducing the loss due to non-congruity. It follows that $m_1/m_2 > b_1/b_2$ is a necessary condition for $v_a^{\dagger} = 0$.

The findings in this section pertain to a firm's decision whether to tie incentive compensation to the single most congruent measure available or to employ a mix of more or less congruent performance indicators. As shown, the solution to this question depends on the level of the manager's identification with the firm and the diversity of tasks assigned to the manager. Unlike in the single-task setting, the stewardship value of the additional measure is not unambiguously decreasing in the manager's identification with the firm. In particular, our analysis indicates that firms with an intermediate level of identification are more likely to apply some mix of performance measures than low-identification firms. The intuition for this result follows our previous finding that the congruity of a performance measure *vis-à-vis* its precision becomes less important in a multi-task setting, the more a manager identifies with his firm. More generally, given that managers vary considerably with respect to how strongly they identify with firms (Boivie et al. 2011), our findings provide a possible explanation for the observed heterogeneity in the number and type of performance measures used within industries.

IV. CONCLUDING REMARKS

This study extends a LEN model to allow a risk- and effort-averse agent to identify with an organization such that the agent's utility declines as his actions deviate from effort-standards set by the principal. We analyze the impact of the agent's identity preferences on optimal performance standards, incentive rates and ratios, the agent's effort, and the value of information for performance evaluation and compensation.

Our model yields comparative statics that provide predictions concerning how additional factors will affect performance-contingent compensation. In practice, managers vary considerably with respect to how strongly they identify with their organization (Boivie et al. 2011). For example, a manager's identification is likely to increase in his job tenure as managers adopt organizational standards to reduce cognitive dissonance and emotional distress rather than leaving the organization. We also expect identification to be increasing in the strength and the saliency of an organization's ideology or culture as managers self-select into organizations whose values and standards they share and in the resources an organization spends to influence its members' identities. Moreover, critical events such as corporate identity initiatives or hostile takeovers can boost or undermine managers' identity. Thus, firm owners face an additional reason to customize contracts to managerial characteristics.

Our analysis reveals that a positive impact of identity on monetary incentives is driven by the multi-task environment. Therefore, our findings suggest that the necessity to control for identity becomes more important as the managers' activities become more diverse. Assuming that higher-level managers are more often confronted with multiple tasks, we would expect that complementarities between identity preferences and monetary rewards are more pronounced at higher hierarchical levels. An interesting extension to our setting is the endogenous nature of a firm's task assignment problem. In particular, we would expect that employees who strongly identify with their firms are generally assigned more diverse tasks than employees who identify weakly or not at all with their firm. For the same reason, we would expect firms to invest more in fostering their employees' identification with them, the more their business model requires their employees to take care of more diverse tasks that are difficult to measure.

Our model is a first step toward the analysis of identity preferences and the design of incentive and information systems. Understanding the interplay among these factors may provide guidance for future empirical work involving managers' identities. Clearly, our results are subject to the caveat of being based on simple representations of the agent's identity preferences, together with the restriction to linear contracts that is common to LEN models. Despite this limitation, we expect the economic mechanisms that cause identity incentives and monetary rewards to be partial substitutes or partial complements to continue to hold for optimal contracts.

APPENDIX A
PROOFS

Lemma 1

Setting (2) equal to zero and re-arranging yields (5a). Setting (1) equal to zero and solving for f yields $f^{\dagger}$. Substituting $f^{\dagger}$ in (4) and using (5a) yields the principal's unconstrained maximization problem:

$$\Pi(f^{\dagger}, v, s, a^{\dagger}) = b(1+\gamma)^{-1}(vm+\gamma s) - \tfrac{1}{2}\gamma(1+\gamma)^{-1}s^2 - \tfrac{1}{2}[(1+\gamma)^{-1}m^2 + r\sigma^2]v^2. \tag{A1}$$

Note that $\Pi(f^{\dagger},v,s,a^{\dagger})$ is separable in s and v. Differentiating (A1) with respect to s and v, setting the derivatives equal to zero and solving for s and v yields (5b) and (5c). ■

Proposition 1

(i) Substituting (5b) and (5c) into (5a) yields:

$$a^{\dagger} = \left(m^2 + r(1+\gamma)\sigma^2\right)^{-1}(m^2 + r\gamma\sigma^2))b \leq b. \tag{A2}$$

(ii) Applying l'Hôspital's rule yields $\lim_{\gamma\to\infty} a^{\dagger} = b$.

(iii) and (iv) Differentiating (A2) and (5b) with respect to γ establishes the claim. ■

Lemma 2

The agent's certainty equivalent with two performance measures is characterized by:

$$CE(z,a) = f + (vm + \gamma s)a - \tfrac{1}{2}(1+\gamma)a^2 - \tfrac{1}{2}\{r(v^2\sigma^2 + 2vv_e\rho\sigma\sigma_e + v_e^2\sigma_e^2) + \gamma s^2\}. \tag{A3}$$

The agent's action choice is characterized by the solution to $\partial CE(z,a)/\partial a = 0$. Setting (A3) equal to zero and solving it for f yields $f^\dagger$. Substituting $f^\dagger$ and $a^\dagger$ in (4) yields the principal's unconstrained optimization problem. Solving the first-order conditions with respect to v, v_e, and s for the three variables yields (8a), (8b), and $s^\dagger = b$. Substituting these results in the unconstrained maximization problem yields (8c). ■

Proposition 2

(i) Dividing (8b) by (8a) yields $v_e{}^\dagger / v^\dagger = -\rho\sigma/\sigma_e$. Taking the derivative with respect to γ, and, for (ii), differentiating (9) with respect to γ establishes the claim. ■

Lemma 3

The agent's certainty equivalent in the two-task setting is given by:

$$CE(z,a_1,a_2) = f + v(ma_1 + m_2a_2) - \tfrac{1}{2}(a_1^2 + a_2^2) - \tfrac{1}{2}\gamma[(s_1 - a_1)^2 + (s_2 - a_2)^2] - \tfrac{1}{2}rv^2\sigma^2. \tag{A4}$$

Differentiating (A4) with respect to a_1 and a_2 yields the agent's effort choices $a_1{}^\dagger$ and $a_2{}^\dagger$. Setting (A4) equal to zero, solving for f, and substituting the result in (4) yields the principal's optimization problem:

$$\Pi(\eta_1, s_1, s_2, v, a_1, a_2) = b_1a_1 + b_2a_2 - \tfrac{1}{2}(a_1^2 + a_2^2) - \tfrac{1}{2}\gamma[(s_1 - a_1)^2 + (s_2 - a_2)^2] - \tfrac{1}{2}rv^2\sigma^2. \tag{A5}$$

Substituting $a_1{}^\dagger$ and $a_2{}^\dagger$ in (A5), differentiating the result with respect to v, s_1, and s_2, and solving the first-order conditions for these variables yields (10a) and (10b). Substituting $a_1{}^\dagger$ and $a_2{}^\dagger$ plus (10a) and (10b) in (A5) yields (10c). ■

Proposition 3

The proof is organized as follows: We first show the derivative of a_i with respect to γ and characterize the condition for $\partial a_i{}^\dagger/\partial\gamma < 0$, $i = 1,2$. Using this characterization, we establish the sufficient condition in (iii) and then show that the two necessary conditions in (i) and (ii) must hold. Differentiating (11a) with respect to γ yields:

$$\frac{\partial a_i^\dagger}{\partial\gamma} = \frac{b_i(m_l^2 + r(1+\gamma)\sigma^2)^2 + b_i m_1^2 m_2^2 - b_l m_1 m_2(m_1^2 + m_2^2 + 2r(1+\gamma)\sigma^2)}{(1+\gamma)^2(m_1^2 + m_2^2 + r(1+\gamma)\sigma^2)^2}, \tag{A6}$$

$i, l = 1, 2$ and $i \neq l$.

Setting $\partial a_i{}^\dagger/\partial\gamma < 0$ and rearranging terms yields the following condition for $\partial a_i{}^\dagger/\partial\gamma < 0$:

$$\frac{b_i}{m_i} < \frac{b_l}{m_l} \cdot \frac{m_l^2(m_1^2 + m_2^2 + 2r(1+\gamma)\sigma^2)}{(m_l^2 + r(1+\gamma)\sigma^2)^2 + m_1^2 m_2^2}. \tag{A7}$$

(iii) The right-hand side of (A7) is monotonically decreasing in γ and goes to zero for $\gamma \to \infty$.

This indicates that for $\partial a_i{}^\dagger/\partial\gamma < 0$ to hold, γ cannot exceed a certain threshold, γ_c. Setting (A7) to equal zero and solving for γ provides γ_c:

$$\partial a_i^\dagger/\partial\gamma = 0 \text{ if } \gamma = \gamma_c = \frac{b_l m_1 m_2 - b_i(m_l^2 + r\sigma^2) + \sqrt{m_1 m_2 (b_l m_i - b_i m_l)(b_1 m_1 + b_2 m_2)}}{r b_i \sigma^2}. \tag{A8}$$

(i) Substituting $b_i/m_i = b_l/m_l$ in (A8) yields $\gamma_c < 0$.

(ii) The numerator of the right-hand side in (A8) is negative for high values of r. This indicates that for $\gamma_c > 0$, it has to be the case that $r < r_c$, where r_c yields a zero numerator in (A8), i.e.:

$$r_c = (b_i\sigma^2)^{-1}\left[m_l(b_l m_i - b_i m_l) + \sqrt{m_1 m_2 (b_l m_i - b_i m_l)(b_1 m_1 + b_2 m_2)}\right]. \ \blacksquare$$

Proposition 4

Taking the derivative of the numerator in (12) with respect to γ establishes the claim. ■

Lemma 4

The agent's certainty equivalent is given by:

$$\begin{aligned} CE(z, a_1, a_2) = {} & f + v(m_1 a_1 + m_2 a_2) + v_a m_a a_1 - \tfrac{1}{2}(a_1^2 + a_2^2) - \tfrac{1}{2}\gamma[(s_1 - a_1)^2 + (s_2 - a_2)^2] \\ & - \tfrac{1}{2} r(v^2\sigma^2 + v_a^2\sigma_a^2). \end{aligned} \tag{A9}$$

Differentiating (A9) with respect to a_1 and a_2 and solving the first-order conditions for these variables yields the agent's effort choices $a_1{}^\dagger$ and $a_2{}^\dagger$. Setting (A9) to equal zero, solving for f, and substituting the result in (4) yields the principal's optimization problem:

$$\Pi(z, a_1, a_2) = b_1 a_1 + b_2 a_2 - \tfrac{1}{2}(a_1^2 + a_2^2) - \tfrac{1}{2}\gamma[(s_1 - a_1)^2 + (s_2 - a_2)^2] - \tfrac{1}{2} r(v^2\sigma^2 + v_a^2\sigma_a^2). \tag{A10}$$

Substituting $a_1{}^\dagger$ and $a_2{}^\dagger$ in (A10), differentiating the result with respect to v, v_a, s_1, and s_2, and solving the first-order conditions for these variables yields (14a), (14b), and (14c). Substituting $a_1{}^\dagger$ and $a_2{}^\dagger$ plus (14a), (14b), and (14c) in (A10) yields (14d). ■

Proposition 5

(i) Differentiating Expression (14b) with respect to γ, setting $\partial v^\dagger/\partial\gamma > 0$, and solving the result for γ yields:

$$\gamma' = \frac{-\sigma\left(b_2 m_2 m_a^2 + r\sigma_a^2(b_1 m_1 + b_2 m_2)\right) + m_a\sqrt{m_1 m_2\left((b_1 m_2 - b_2 m_1)(b_1 m_1 + b_2 m_2)\sigma_a^2 - b_1 b_2 m_a^2 \sigma^2\right)}}{r\sigma\sigma_a^2(b_1 m_1 + b_2 m_2)}.$$

Differentiating (14c) with respect to γ, setting $\partial v_a{}^\dagger/\partial\gamma > 0$, and solving the result for γ yields:

$$\gamma'' = \frac{\sigma_a m_a(b_2 m_1 - b_1 m_2) - r\sigma^2\sigma_a b_1 + \sqrt{m_1 m_2\left((b_2 m_1 - b_1 m_2)(b_1 m_1 + b_2 m_2)\sigma_a^2 + b_1 b_2 m_a^2\sigma^2\right)}}{r\sigma^2\sigma_a b_1}.$$

(ii) Substituting (14b) and (14c) in $IR = v^\dagger/v_a{}^\dagger$ yields the incentive ratio. Differentiating $IR^\dagger$ with respect to γ yields:

$$\partial IR^{\dagger}/\partial\gamma = rm_2 \frac{(b_1m_2 - b_2m_1)(b_1m_1 + b_2m_2)\sigma_a^2 - b_1b_2m_a^2\sigma^2}{m_a\left(b_2m_1m_2 - b_1\left(r(1+\gamma)\sigma^2 + m_2^2\right)\right)^2}.$$

Substituting $b_1/m_1 < b_2/m_2$ establishes the claim. ■

Proposition 6

(i) Setting $r = 0$ in (15) and differentiating with respect to γ yields:

$V^{\dagger}(\eta_2|\eta_1) = -\frac{1}{2}(1+\gamma)^{-2}(m_1^2 + m_2^2)^{-1}(m_2^2)^{-1}[m_2(b_1m_2 - b_2m_1)]^2 < 0.$

(ii) Letting r grow to infinity in (15) yields:

$\lim_{r\to\infty} V^{\dagger}(\eta_2|\eta_1) = 0.$

(iii) From (15), $V^{\dagger}(\eta_2|\eta_1) = 0$ for $\gamma = \gamma_{\lambda} \equiv (m_2/m_1 - b_2/b_1)\, m_1m_2 /(r\,\sigma^2) - 1$, and $\gamma_{\lambda} > 0$ for $b_1m_2 - b_2m_1$ sufficiently positive. Moreover, $\partial V^{\dagger}(\eta_2|\eta_1)/\partial\gamma > 0$ if $\gamma = \gamma_{\lambda}$. ■

APPENDIX B

IDENTITY PREFERENCES IN A MULTI-TASK LEN SETTING

This section establishes that the optimal standards chosen by the principal in a setting with quadratic identity- and effort-cost functions are independent of the agent's degree of internalization of the standards (which implies $s_i^{\dagger} = b_i$), irrespective of the number of tasks that the agent is responsible for and irrespective of the characteristics of the information system available for contracting.

B.1 Agent's Preferences, Information System, and Action Choices

Assume the agent controls n activities that influence the payoff to the principal and let the vector $\mathbf{a} \in \Re^n$ represent his choice of effort levels. The personal cost of effort is assumed to be:

$$\kappa(\mathbf{a}) = \tfrac{1}{2}\,\mathbf{a}'\boldsymbol{\Gamma}_{\mathbf{a}}\mathbf{a},$$

where $\boldsymbol{\Gamma}_{\mathbf{a}}$ is a $n \times n$ symmetric, positive-definite matrix of effort cost parameters.

The agent's personal cost of deviating from the standard is assumed to be:

$$\kappa_s(\mathbf{s}, \mathbf{a}) = \tfrac{1}{2}(\mathbf{s} - \mathbf{a})'\boldsymbol{\Gamma}_{\mathrm{s}}(\mathbf{s} - \mathbf{a}),$$

where the symmetric, positive-definite matrix $\boldsymbol{\Gamma}_{\mathrm{s}}$ represents the agent's degree of internalization of the standards.

The information system discloses a $m \times 1$-vector $\mathbf{y}$ of performance measures at date 2, i.e., $\mathbf{y} = \mathbf{M}\,\mathbf{a} + \boldsymbol{\varepsilon}$, where $\mathbf{M}$ is a $m \times n$-matrix of sensitivities of the signals to the agent's effort levels in his n tasks, and $\boldsymbol{\varepsilon}$ is a $m \times 1$-vector of normally distributed noise terms with $\boldsymbol{\varepsilon} \sim \mathrm{N}(\mathbf{0},\boldsymbol{\Sigma})$, and $m \times m$-covariance matrix $\boldsymbol{\Sigma}$.

At date 0, the principal offers the agent a contract, represented by $z = (f,\mathbf{v},\mathbf{s})$, where $\mathbf{s}$ is the standard specified by the principal and $\mathbf{v}$ is the agent's $m \times 1$ vector of incentive rates for each performance measure. Hence, the agent's compensation given performance measures $\mathbf{y}$ and contract z is $w(\mathbf{y},z) = f + \mathbf{v}'\mathbf{y}$. Applying the specifications to the agent's utility provides the following certainty equivalent:

$$CE(z, \mathbf{a}) = f + (\mathbf{M}'\mathbf{v} + \boldsymbol{\Gamma}_{\mathrm{s}}\mathbf{s})'\mathbf{a} - \tfrac{1}{2}\,\mathbf{a}'(\boldsymbol{\Gamma}_{\mathbf{a}} + \boldsymbol{\Gamma}_{\mathrm{s}})\mathbf{a} - \tfrac{1}{2}(r\mathbf{v}'\boldsymbol{\Sigma}\mathbf{v} + \mathbf{s}'\boldsymbol{\Gamma}_{\mathrm{s}}\mathbf{s}). \tag{B1}$$

Differentiating (B1) with respect to **a**, given contract z, provides the agent's action choice:

$$\mathbf{a}^{\dagger}(\mathbf{v},\mathbf{s}) = (\mathbf{\Gamma_a} + \mathbf{\Gamma_s})^{-1}(\mathbf{M}'\mathbf{v} + \mathbf{\Gamma_s s}). \tag{B2}$$

The resulting certainty equivalent (substituting (B2) into (B1)) is:

$$CE^{\dagger}(z) = f + ½(\mathbf{M}'\mathbf{v} + \mathbf{\Gamma_s s})'(\mathbf{\Gamma_a} + \mathbf{\Gamma_s})^{-1}(\mathbf{M}'\mathbf{v} + \mathbf{\Gamma_s s}) - ½(r\mathbf{v}'\mathbf{\Sigma}\mathbf{v} + \mathbf{s}'\mathbf{\Gamma_s s}). \tag{B3}$$

Again, the agent will only participate in the firm if his contract z is such that it provides him with his reservation certainty equivalent, which is scaled to equal zero, i.e.:

$$CE^{\dagger}(z) \geq 0. \tag{B4}$$

B.2 Principal's Preferences and Contract Choice

The expected gross value of the firm is assumed to be a linear function of the effort expended by the agent and is represented by $E[\mathrm{x}|\mathbf{a}] = \mathbf{b}'\mathbf{a}$, where the vector $\mathbf{b} \in \Re^{n}$ represents the agent's productivity with respect to the principal's payoff. The expected net terminal value of the firm is:

$$\Pi = E[x - w|\mathbf{a}]. \tag{B5}$$

To obtain the optimal contract, the principal chooses z to maximize (B5) subject to (B2) and (B4). Choosing f such that $CE^{\dagger}(z) = 0$ and substituting $f^{\dagger}$ and (B2) into (B5) gives the principal's unconstrained decision problem:

$$\begin{aligned}\Pi^{\dagger}(\mathbf{v},\mathbf{s}) = {} & \mathbf{b}'(\mathbf{\Gamma_a} + \mathbf{\Gamma_s})^{-1}\mathbf{M}'\mathbf{v} - ½\,\mathbf{v}'\left(\mathbf{M}(\mathbf{\Gamma_a} + \mathbf{\Gamma_s})^{-1}\mathbf{M}' + r\mathbf{\Sigma}\right)\mathbf{v} + \mathbf{b}'(\mathbf{\Gamma_a} + \mathbf{\Gamma_s})^{-1}\mathbf{\Gamma_s s} \\ & - ½\,\mathbf{s}'\mathbf{\Gamma_a}(\mathbf{\Gamma_a} + \mathbf{\Gamma_s})^{-1}\mathbf{\Gamma_s s}.\end{aligned} \tag{B6}$$

Optimizing (B6) with respect to each incentive rate in **v** and each standard in **s** results in the following characterization of the optimal incentive rates and standards:

$$\mathbf{v}^{\dagger} = \mathbf{Q}^{-1}\mathbf{M}(\mathbf{\Gamma_a} + \mathbf{\Gamma_s})^{-1}\mathbf{b}, \tag{B7a}$$

$$\mathbf{s}^{\dagger} = \mathbf{\Gamma_a^{-1}}\mathbf{b}, \tag{B7b}$$

with:

$$\mathbf{Q} \equiv \mathbf{M}(\mathbf{\Gamma_a} + \mathbf{\Gamma_s})^{-1}\mathbf{M}' + r\mathbf{\Sigma}.$$

Thus the standard is solely influenced by the marginal cost and productivity of the agent's effort choice and is set equal to the first-best effort level.

Do Financial Statement Users Judge Relevance Based on Properties of Reliability?

ABSTRACT: Relevance and reliability (now referred to as "representational faithfulness") are qualities of financial information that both the Financial Accounting Standards Board and the International Accounting Standards Board use in setting standards for financial reporting. Despite their importance, very little research has addressed how financial statement users apply these constructs. Via experiments set within the fair value context, we show that users do not view them as independent constructs. Instead, variations in properties that are associated with the *reliability* of a measurement influence users' assessments of the *relevance* of fair value. The relationship between assessed relevance and assessed reliability is unidirectional, in that factors underlying reliability influence judgments of relevance, but factors underlying relevance do not influence judgments of reliability. Our findings are important because inappropriate assessments of relevance can influence firm valuation. The results are particularly meaningful in the context of fair value because such measurements can vary widely in reliability.

I. INTRODUCTION

Relevance and reliability (now referred to as "representational faithfulness") are important qualities of financial reporting that both the Financial Accounting Standards Board (FASB) and the International Accounting Standards Board (IASB) use in setting standards (FASB 2010; IASB 2010).[1] Relevance addresses the pertinence of an economic construct (e.g., fair value, historical cost) to a user's decision. Reliability addresses how well that economic construct, or phenomenon, is depicted or measured (e.g., fair value based on a market transaction versus a model). Standard setters note that although relevance and reliability are both necessary for information to be useful in decision making, information can be relevant without being reliable and can be reliable without being relevant (FASB 2010, ¶QC 17).[2] In this paper, we assert and experimentally test the idea that financial statement users conflate these two constructs when judging the relevance of fair value measurement; that is, we test the idea that users do not view these two constructs as independent.

Investigating how financial statement users think about the constructs of relevance and reliability in the context of fair value measurement is important for several reasons. First, we lack empirical evidence regarding how users assess these qualities. Even the limited research and debates to date suggest that the answer is unclear. Some researchers indicate that users view relevance and reliability as inversely related (e.g., Schipper 2003; Dye and Sridhar 2004), while others assert a positive relationship (McCaslin and Stanga 1983; Duncan and Moores 1988). Second, one potential reason why many financial statement users oppose fair value accounting may originate in their conflating the concepts of relevance and reliability. Indeed, some of the criticisms raised against fair value accounting during the recent financial crisis appear to be due to individuals judging the relevance of fair value based on the reliability of its measurements (American Bankers Association 2009). By providing scholarly evidence on this issue, we provide to standard setters information that will help them make important decisions about fair value measurements in accounting.

In this paper, we report the results of several experiments in which we investigate the hypothesis that financial statement users' assessments of the relevance of an economic construct are influenced by factors (i.e., potential for bias and error) underlying the reliability of its measurement. We examine this idea in the context of fair value measurement of an asset, as relevance and reliability issues are of particular practical concern there.[3] Finally, we also investigate the economic importance of our ideas by determining whether the relationships noted above influence users' judgments about a firm's valuation.

Our hypotheses are grounded in psychology theories about attribute substitution (Kahneman and Frederick 2002). Attribute substitution is a heuristic used by individuals asked to evaluate a difficult-to-assess attribute. The theory predicts that when asked to evaluate a less accessible attribute, individuals often (without awareness) substitute an evaluation of a more accessible attribute of the same entity. The accessibility of an attribute relates to an individual's ability to conceptualize the value of an attribute, with increases in accessibility due, in part, to the frequency with which the attribute is evaluated as part of perception and comprehension (Kahneman and Frederick 2002). We provide evidence that reliability is a basic property of fair value measurement that users understand well. On the other hand, relevance is decision specific and requires a more difficult, case-by-case analysis. Thus, we maintain that in the fair value context, reliability is a more accessible attribute than is relevance. We, therefore, predict that users will substitute the more accessible assessment of measurement reliability when asked to assess the relevance of a fair value.

---

[1] The FASB and IASB recently replaced the term "reliability" with "representational faithfulness" to address the possibility that auditors would associate reliability with vouchability in addition to the factors it was intended to incorporate (Schipper 2005). This modification to the conceptual framework does not affect our study because we examine features of reliability (i.e., error and bias) that are unrelated to the change. We use the more familiar term, reliability, herein.

[2] The FASB distinguishes relevance and reliability from a third construct, decision usefulness. They note that "[i]nformation must be both relevant and faithfully represented if it is to be useful. Neither a faithful representation of an irrelevant phenomenon, nor an unfaithful representation of a relevant phenomenon, helps users make good decisions" (FASB 2010, ¶QC 17). Their comments imply that an unreliable measure of a highly relevant phenomenon does not diminish the relevance of the phenomenon to the decision, but reduces the decision usefulness of the information.

[3] Although our paper is set in the context of fair value, it does not address the issue of whether fair value is more or less relevant than historical cost (see Koonce et al. [2011] for a study of that issue). Rather, our study focuses on how the judged relevance of fair value is influenced by variations in the reliability of its measurement.

The results of our experiments support our hypothesis that variations in factors associated with the reliability of an asset's fair value measurement affect financial statement users' assessments of the relevance of a fair value. Specifically, we find that a measurement's source and method of derivation (i.e., a market transaction versus a model) strongly influence users' judgments about relevance. Because attribute substitution is unidirectional, users substitute evaluations of more accessible attributes for evaluations of less accessible attributes. However, the opposite does not occur. Accordingly, we also show that manipulations of factors underlying relevance do not affect users' assessments of reliability. Finally, results support the idea that because of this attribute substitution, factors underlying reliability may be over-weighted in users' valuation judgments; that is, these factors influence valuation not only through their effect on assessed reliability, but also through their influence on assessed relevance. While we cannot establish a normative benchmark for valuation in our experiment, these results suggest that properties underlying reliability have too much emphasis in valuation.

Our study has several important implications. First, our results shed light on one reason that efforts of the FASB and the IASB to extend the use of fair values in financial reports are being met with resistance. We show that acceptance of the concept of fair value measurement may be conditioned primarily on how well the items are measured rather than on separate assessments of the relevance of the economic construct of fair value and the reliability of its measurement. This idea finds anecdotal support when, during the recent financial crisis, observers argued that thin markets and unreliable measurements created fair value accounting outcomes that were not relevant to decision makers (American Bankers Association 2009). We believe our study is important to this debate; it indicates that at least part of the reason users argue against the use of fair value may be that they do not consider reliability and relevance to be independent constructs. The primacy of reliability in users' minds may indicate that standard setters should focus on standards that enhance the reliability of fair value measurements in order to make the biggest gains in acceptance of fair value. Additionally, standard setters may wish to focus on ways to better communicate the importance of relevance of particular constructs separate from their efforts to improve the reliability of the measurements.

Second, users' conflation of the qualities of reliability and relevance may hamper additional attempts to improve the actual reliability of fair value measures or the communication of reliability. Although the FASB has previously issued guidance about the communication of fair value measurement reliability (e.g., SFAS 157), we argue that further efforts to improve those disclosures may be thwarted if users are unable to consider the relevance of the fair value construct *independent of* the reliability of its measurement. By documenting that users do not view these two qualities separately, we hope that our study provides a foundation for greater clarity on what can be improved (i.e., measurement reliability or its disclosure) and what is relatively fixed (i.e., relevance).

Third, our results suggest that financial statement users' conflation of relevance and reliability may influence their valuation judgments. That is, strengths or deficits in reliability due to potential error appear to be over-weighted in valuations. The natural next question is whether users' association of relevance with reliability can be moderated. Our theory and results are consistent with the ideas of attribution substitution theory, which implies that decision makers are *unaware* of the substitution. However, we did not explicitly test this assumption. Psychology researchers have long struggled with determining how individuals unconsciously evaluate their environment, judge other individuals, and undertake actions, all while consciously thinking about something else (Wilson 2002). A better understanding of whether financial statement users are aware of the attribute substitution is important, as the success of attempts to moderate its effects is likely contingent on their awareness. Stated differently, if decision makers are unaware of the attribute substitution, then training in assessing relevance may not be sufficient to correct their behavior (e.g., see Tversky and Kahneman 1974).

In the following section, we develop our theoretical predictions. Sections III and IV describe our two primary experiments, respectively. Section V provides robustness tests and Section VI summarizes and concludes the paper.

II. HYPOTHESES DEVELOPMENT

The Independence of Relevance and Reliability

Relevance and reliability are the two primary qualitative characteristics of accounting information that determine its usefulness in decision making (FASB 1980, 2010). Relevance applies to a construct, a type of information. Reliability, on the other hand, is a property of a specific measurement of that construct. Both relevance and reliability influence the reported measure's decision usefulness (FASB 2010, ¶ QC17).

In its conceptual framework, the FASB notes that information must be both relevant and reliable to be useful, and that neither a reliable depiction of an irrelevant phenomenon nor an unreliable depiction of a relevant phenomenon is decision useful (FASB 2010, ¶ QC17). The FASB's comments imply that all four cells of a 2 (relevance: lower, higher) × 2 (reliability: lower, higher) matrix could be populated, as illustrated in Panel A of Figure 1. The FASB further suggests to preparers that when considering a particular decision, they should follow a sequence of steps, looking first for the most relevant information for that decision and then ascertaining the reliability of a measure of that information. If that information is lacking in reliability (or is just not available), then the decision maker should select the next most relevant measure, then again check its reliability. This process is repeated as necessary (FASB 2010, ¶ QC18; IASB 2010, ¶ QC18). Although many assert that the FASB's conceptual framework is *suggestive* of the independence of relevance and reliability (Maines and Wahlen 2006; Li et al. 2010), the framework does not *explicitly* state that the concepts are independent, and so the FASB's view on this issue is unknown.

Although the FASB's conceptual framework is unclear on the idea that relevance and reliability are independent qualities—that is, that a particular level of one does not imply a particular level in another—viewpoints outside of accounting maintain that the two constructs should be viewed as independent. In marketing, information usefulness is deemed a function of its diagnosticity (i.e., relevance) and, separately, its reliability (Dick et al. 1990). In law, information is useful if it is admissible (i.e., has relevance) and has probative value (i.e., is reliable) (Mueller and Kirkpatrick 1995). In research settings, a construct is useful if it is relevant and its measurement is reliable (Herzog 1997).

The following example, outside of the financial reporting context, helps to illustrate the view that relevance and reliability are distinct and independent constructs. Consider an individual who is spending the day in Chicago. For that individual, the air temperature in Honolulu is not highly relevant to his decision about whether to wear an overcoat when going outside. Nonetheless, the

FIGURE 1
Relevance and Reliability as Independent Constructs

Panel A: Relevance and Reliability for a Decision about What Value to Place on an Asset

	Lower Reliability	**Higher Reliability**
Lower Relevance	Model estimate without comparables, Stand-alone value of asset in use	Comparable sales value, Stand-alone value of asset in use
Higher Relevance	Model estimate without comparables, Stand-alone value of asset held for sale	Comparable sales value, Stand-alone value of asset held for sale

Panel B: Relevance and Reliability for a Decision about Whether to Wear an Overcoat in Chicago

	Lower Reliability	**Higher Reliability**
Lower Relevance	Broken thermometer, Today's Honolulu temperature	Accurate thermometer, Today's Honolulu temperature
Higher Relevance	Broken thermometer, Today's Chicago temperature	Accurate thermometer, Today's Chicago temperature

temperature in Honolulu can be measured by a very unreliable process or instrument, or by a very reliable one. The air temperature in Chicago, on the other hand, is highly relevant to the individual for the decision about whether to wear an overcoat. Likewise, the temperature in Chicago can be measured by a very unreliable process or instrument, or by a very reliable one. Indeed, the construct of "Chicago air temperature" is relevant to the person in Chicago; the reliability of the current measurement of the Chicago temperature is a separate, independent factor that the decision maker must consider.

Do Users View Them as Independent?

While we argue that the constructs of reliability and relevance should be viewed as independent, we also question whether financial statement users judging the relevance of fair value treat them as such. As explained more fully below, prior research indicates that financial statement users have fairly accurate ideas about how to assess reliability, and so we expect that they will be able to do so readily. On the other hand, they are less likely to have a ready framework for assessing relevance, particularly in the fair value context (Koonce et al. 2011). As a result, we posit that they will rely on attribute substitution to judge fair value relevance (Kahneman and Frederick 2002). That is, they are likely to substitute an easier question (i.e., how reliable is this fair value measure?) when asked the relatively difficult question "how relevant is fair value?" We explain our argument in more detail below.

Reliability is a basic property of information, and individuals are well acquainted with its determinants. To support this assertion, we note that numerous studies in accounting and psychology provide evidence that individuals understand that factors underlying reliability, such as the objectivity of the measurement source and the error-proneness of that source, affect the assessed decision usefulness of a reported measure. For example, Hirst (1994) showed that auditors discount the inferential value of information obtained from sources that are low in competence or objectivity relative to that of information obtained from sources higher in these characteristics. Similarly, market participants discount forecasts made by management with low prior accuracy in forecasting earnings relative to those with high prior accuracy (Williams 1996; Hirst et al. 1999). Moreover, market participants' reactions to management forecasts are, in part, a function of the credibility of management (Jennings 1987). Investors glean manager credibility from factors such as their competence, trustworthiness, and situational incentives (Mercer 2004). Additional studies indicate that users of other forms of financial reporting can identify when a source is more or less credible and will utilize the information accordingly. For example, users' assessments of financial analysts' credibility depend, in part, on analysts' prior accuracy, and users' willingness to purchase future reports from these analysts is associated with their assessments of analysts' credibility (Kadous et al. 2009). We thus propose that reliability is relatively easy to assess and, therefore, is likely to be an accessible attribute for most users.

Unlike reliability, the relevance of an item depends on the specific decision to be made and its context (FASB 1980, 2010, ¶ BC3.11). Because each situation is unique, users are less likely to have a ready schema for assessing relevance. That is, rather than relying on well-established relationships (e.g., more competent sources tend to produce more reliable measurements), users have to carefully evaluate their decision task and decision context to assess relevance. There are limited circumstances in which relevance is easy to assess (e.g., judging the relevance of the air temperature in Chicago to the decision to wear a coat). However, based on prior research by Koonce et al. (2011), we propose that in the fair value context, relevance is a less accessible attribute than reliability (also see Joyce et al. [1982] and Jurney [2008] for evidence supporting this idea in financial reporting, more generally).[4]

Because assessing the relevance of fair value will be difficult for financial statement users, we believe that attribute substitution will apply (Kahneman and Frederick 2002). In general, a person who is asked a question about an accessible (i.e., easily retrievable from their knowledge) attribute such as reliability can answer the question directly and easily. In contrast, a person who is asked a difficult question will follow a different process. The individual, being unable to access information about the target attribute, will instead answer an easier question about a more accessible attribute of the same entity or object (Kahneman 2002, 469).

In our fair value setting, we argue that the more accessible attribute is reliability and the less accessible attribute is relevance. Thus, we propose that financial statement users asked to assess the reliability of a fair value measurement of a financial statement item will readily respond to that question, as reliability is an accessible attribute. In contrast, financial statement users will have difficulty responding to a question asking them to assess the relevance of an item's fair value because relevance is less accessible. Following the logic of attribute substitution, users asked to assess relevance will instead answer an easier question about the reliability of the measurement of the financial statement item in question. In other words, they will assess the relevance of a reported economic construct by assessing how well it represents, or is similar to, a reliable measurement.[5] This reasoning implies that financial statement users will not only use factors underlying the reliability of a measurement in assessing its reliability, but they will also rely on those same variables in assessing relevance. This logic leads to our first hypothesis:

---

[4] While these studies demonstrate users' relative difficulty in assessing relevance versus reliability, they do not address why this occurs nor do they test our hypothesis that variations in properties associated with reliability influence relevance judgments.

> **H1:** Factors underlying the *reliability* of a fair value measurement influence financial statement users' assessments of the *relevance* of fair value information.

Although our theory predicts that assessments of reliability and relevance will be positively associated, it is important to note that we also expect that the relationship is unidirectional. Manipulations of factors underlying the reliability of a measurement will influence assessments of the reported construct's relevance (and, of course, of measurement reliability). However, we do not expect the opposite relationship to hold—that is, manipulations of factors underlying relevance will not affect users' assessments of reliability. The latter is unlikely to occur because reliability is a relatively accessible attribute and so users will be able to readily answer a question about reliability.

The decision usefulness of information is a function of both its relevance and its reliability (FASB 1980, 2010). Thus, we expect users will rely on their own assessments of the relevance and reliability of information in determining how useful that information is for subsequent decisions, such as valuation. If variations in properties underlying reliability affect assessments of reliability, as is appropriate, but also affect assessments of relevance (H1), and if users incorporate assessments of both relevance and reliability into their valuation judgments, then variations in the properties underlying reliability will influence valuation through two distinct paths—one through users' assessments of the relevance of the item and another through their assessments of the reliability of the item's measurement. We summarize this prediction in the following hypothesis:

> **H2:** Factors underlying the *reliability* of a measurement influence financial statement users' valuation judgments via two effects—one through assessed reliability and a second through assessed relevance.

Two caveats apply. First, Kahneman and Frederick (2002, 53) indicate that attribute substitution usually occurs without decision maker awareness. Indeed, those who substitute one question for another simply fail to notice they are answering a different question (Kahneman 2002, 469). Although we rely on the idea of attribute substitution for our predictions, we do not test the assumption that individuals are unaware of the substitution. Second, although it is difficult to establish a normative benchmark for weights that users should apply to various factors when making valuation judgments, our ideas suggest that users place too much weight on the properties underlying reliability when they make valuation judgments. That is, reliability may have too much emphasis in valuation. This idea is consistent with prior research that indicates that highly accessible values tend to be over-weighted in judgments (Strack and Mussweiler 1997; Epley and Gilovich 2002; Chapman and Johnson 2002; Epley and Gilovich 2006).

---

[5] Judgments made in this fashion often are described as following the representativeness heuristic (Tversky and Kahneman 1974).

III. EXPERIMENT 1

Participants, Design, and Variables

We tested our hypotheses in an experiment with 129 M.B.A. students from two *BusinessWeek* top-25 schools.[6] We asked participants to assume the role of a potential investor in a manufacturing firm. All were told that the company had purchased a plot of land for $41 million two years ago. The current value of the land, generated by external consultants who relied on a model, was estimated at $53 million. As explained more fully below, we manipulated two variables relating to properties underlying the reliability and relevance of the land's current value in a 2 × 2 full-factorial, between-participants design. We randomly assigned participants to conditions.

We manipulated the competence of the measurement source (i.e., external consultants) at two levels. Those participants in the high competence (i.e., high reliability) conditions were provided with the following information regarding the consultants:

> Based on your experience and knowledge, you believe the consultants are unbiased, and based on the accuracy of their work you have noted on other valuations, you believe they are highly competent.

We provided participants in the low competence (i.e., low reliability[7]) conditions with the following statement:

> Based on your experience and knowledge, you believe the consultants are unbiased, but based on errors and reasoning flaws you have noted on other valuations, you believe they are not very competent.

Our second manipulation relates to a property we expect financial statement users to associate with relevance—the length of time until management plans to sell the asset (FASB 2006, SFAS 157, ¶20). We manipulated the time to sale at two levels. Approximately half of the participants were told that management intends to sell the plot of land very soon ("sell soon" conditions), which corresponds to higher relevance for the valuation decision we assigned participants. The remaining participants were told that management does not intend to sell the plot of land for at least 20 more years ("no sell" conditions), which corresponds to lower relevance for this decision.

There is debate as to whether time to sale *should* affect relevance judgments in a valuation context (Hague and Willis 1999). While some individuals believe that the relevance of fair values depends on whether something is to be sold soon or sold later, others consider the distinction as unimportant. Our objective is not to resolve this debate, but rather to leverage the finding—as shown in recent research (Koonce et al. 2011)—that, on average, the time to sale is important to investors' relevance judgments in our design. This manipulation allows us to keep constant the measurement basis (i.e., fair value). Other possible ways to manipulate relevance are less desirable

---

[6] Participants came from three sources: 24 were full-time M.B.A. students from one institution (average of 4.7 years of work experience, 4.9 finance classes, 3.1 accounting classes, 71 percent had invested in individual stocks previously and 96 percent plan to do so), 55 were full-time M.B.A. students from a second institution (average of 5.5 years of work experience, 2.5 finance classes, 2.1 accounting classes, 65 percent had invested in stocks previously and 91 percent plan to), and 50 were Executive M.B.A. students from the first institution. Time constraints prevented us from collecting individual demographics from the Executive students; however, the class as a whole averaged 12 years of work experience. Source of participants did not have significant effects on any of our dependent measures.

[7] This manipulation represents higher and lower levels of reliability rather than absolute levels of high and low. For ease of exposition, however, we refer to levels of this variable, as well as other analogous variables in the paper, as "high" and "low" rather than "higher" and "lower."

FIGURE 2
Example of Materials Used in Experiment 1
High Competence, Sell Soon Condition

Several years ago, WRSwann Co., a manufacturing company, purchased a plot of land for $41,000,000.

You learn that management intends to sell the plot of land very soon.

The current value of the land is estimated at $53,000,000. This current value number was generated by external consultants.

Original Value	Consultants' Estimate of Current Value
$41,000,000	$53,000,000

The consultants generated this number with a model that they created. The model uses the market values for several comparable plots of land. However, no individual plot is completely comparable to the one owned by WRSwann, so the model incorporates additional factors that could affect its value (i.e., location, size, desirability, population growth). The weights that are placed on these additional factors can vary depending on the various assumptions made by the consultants.

Based on your experience and knowledge, you believe the consultants are unbiased, and, based on the accuracy of their work you have noted on other valuations, you believe they are highly competent.

as they involve changing the underlying economic information that is communicated (e.g., comparing fair value to historical cost). Figure 2 provides an example of the materials.

After presenting participants with the information described above, we asked for their responses to five questions. Our key dependent variables include assessments of the relevance of "the current value information," the reliability of "the number assigned to the land's current value," and how the "situation" affects the valuation of the firm. We worded these relevance and reliability questions carefully to ensure that participants were asked the relevance question at the construct level (i.e., relevance of current value information) and the reliability question at the operational level (i.e., reliability of its measurement). Participants assessed the relevance of the current value information to their evaluation of the firm on a 101-point scale, with 0 labeled "not at all relevant" and 100 labeled "extremely relevant." The responses to this question serve as the main dependent measure for our first hypothesis. Participants assessed the reliability of the number assigned to the land's value on a 101-point response scale ranging from 0, "very unreliable," to 100, "very reliable."

Participants provided assessments of valuation in two stages. They first assessed whether the situation described in the case materials increases, decreases, or neither increases nor decreases the value they would place on the firm. Those who indicated a change in the value also indicated the magnitude of the change on a 101-point scale, ranging from "slightly increases (decreases) how much I value the company" (0) to "greatly increases (decreases) how much I value the company" (100). We created our valuation dependent variable by coding the magnitude of change as a positive amount for increases in value and a negative amount for decreases in value. This variable is zero for participants who indicated neither an increase nor a decrease in valuation due to the reported information. Two additional questions ask for participants' assessments of the amount of bias in the current value measurement and of management's forthcomingness.[8]

Results

Preliminary Tests

We first assess whether our manipulation of competence influenced participants' judgments of the reliability of the current value number. Participants in the high source competence conditions assessed the reliability of the current value number significantly higher (mean of 67.14) than did those in the low source competence conditions (mean of 45.39) ($F_{1,125} = 42.05$, $p < 0.01$). As expected, neither time to sale nor the interaction of time to sale and source competence significantly influenced reliability assessments (both p-values > 0.30). Also as expected, participants' ratings of bias and management forthcomingness did not significantly differ across levels of source competence (both p-values > 0.10).[9]

Tests of Hypotheses

Descriptive (inferential) statistics for participants' assessments of relevance and their valuation judgments are presented in Panel A (Panel B) of Table 1. Turning first to the relevance dependent measure, the analysis of variance (ANOVA) model reveals a significant main effect of the source competence variable ($F_{1,125} = 10.92$; $p < 0.01$), but no other significant effects. Cell means indicate that participants receiving the measurement from a high competence source viewed the current value information as significantly more relevant (mean of 65.66) than did participants receiving the measurement from a low competence source (mean of 51.44). Thus, financial statement users' determination of the relevance of current value information is based on their determination of the reliability of its measurement, supporting H1.[10] This finding is consistent with our theory, as it implies that evaluations of relevance are based on the more accessible reliability attribute. Further support for participants' reliance on attribute substitution is indicated by a positive and highly significant correlation of their assessments of reliability and relevance ($r = 0.48$, $p < 0.01$) (Kahneman and Frederick 2005).

As noted above, there were no significant effects in the model for participants' relevance ratings other than that of source competence. The manipulation of time to sale did not have the expected effect on ratings of relevance. Thus, we have evidence that source competence influences users' assessments of both reliability and relevance and that time to sale does not influence

---

[8] An alternative approach for Experiment 1 would have been to ask participants about the relevance of fair value and then provide them with the reliability of a specific fair value measurement. Such an approach would have mimicked the process recommended by standard setters in their conceptual frameworks (FASB 2010; ¶ QC18; IASB 2010 ¶ QC18). We did not follow this approach because financial statement users typically receive measures that already have characteristics of relevance and reliability. That is, they typically receive information about both constructs simultaneously. Only preparers and standard setters are likely to be in a situation to consider them in a sequential fashion. Our materials thus mimic this important contextual feature for users.

[9] An ANOVA model for bias revealed a marginally significant main effect of time to sale ($p = 0.085$) and a significant interaction of competence and time to sale ($p < 0.01$). While participants rated bias as approximately equal in the two higher competence conditions, they rated bias as higher for lower competence sources when management had no plans to sell and lower for lower competence sources when management planned to sell the asset soon.

[10] We also manipulated bias (high versus low) in Experiment 1. Bias is an underlying property of reliability and, thus, allows us another opportunity to test our hypothesis about attribute substitution. Holding competence at a high level, our results of this additional manipulation reveal that participants in the low bias condition rated the relevance of the current value information higher than did those in the high bias condition (65.66 for low bias versus 60.29 for high bias), consistent with our predictions. However, this effect is only marginally significant ($p = 0.10$, one-tailed).

Residual	125	615			114	1176		

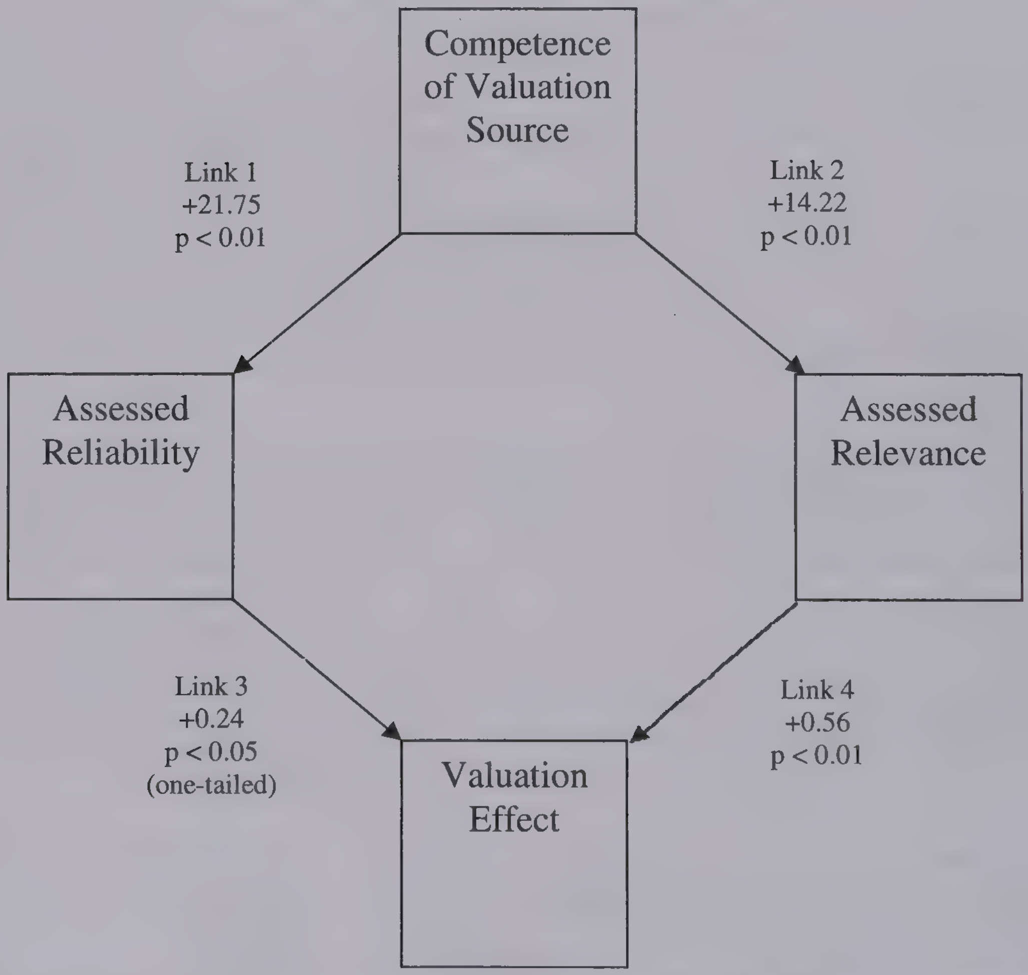
Participants assessed the relevance of the current value information to their overall evaluation of the firm. The competence of the external consultants determining the measurement was varied at two levels, high and low. Management's plans to sell the asset were varied at two levels, sell soon versus no sell. Participants provided relevance assessments on a 101-point scale, with 0 labeled "not at all relevant" and 100 labeled "extremely relevant." Participants also assessed whether the current value information increases, decreases, or neither increases nor decreases the value they place on the firm. Participants who indicated a change in value also indicated the magnitude of the change on a 101-point scale, ranging from "slightly increases (decreases) how much I value the company" (0) to "greatly increases (decreases) how much I value the company" (100). Valuation effect is calculated by coding the magnitude of change as a positive amount for participants who indicated increases in value, a negative amount for those who indicated decreases in value, and 0 for participants who indicated no change in value.

reliability. However, because our manipulation of time to sale did not also affect assessed relevance, we cannot be sure that we have effectively manipulated factors underlying relevance. In sum, Experiment 1 allows us to test our H1 (i.e., manipulations of reliability influence relevance judgments). However, it does not allow us to test the idea that the reliability-relevance relationship is unidirectional (i.e., that manipulation of properties underlying relevance do not result in differences in assessed reliability). We are able to explore the latter issue in Experiment 2.

Table 1 presents participants' valuation judgments. The ANOVA results show a significant main effect of source competence on valuation effects ($F_{1,114} = 8.46$, $p < 0.01$). Consistent with the relevance assessments, participants receiving the measurement from a high competence source indicated more positive valuation effects (mean of 34.24) than did those receiving the measurement from a low competence source (mean of 16.12). Time to sale and the interaction of source competence and time to sale are not significant in the ANOVA.

H2 examines the paths by which properties underlying reliability influence valuation judgments. This hypothesis is important for two reasons. First, although we find support for H1, it is possible that the relationship between manipulated source competence and assessed relevance is not meaningful in the sense of influencing valuation. Second, H2 verifies that users incorporate *both* assessed reliability and assessed relevance in their valuations (i.e., that decision usefulness is a function of both assessments). We test our theory underlying both H1 and H2 using a structural-equations model, as presented in Figure 3. Note that our full hypothesized model would also include a link from manipulated factors influencing relevance (time to sale) to assessed relevance. However, because the manipulation of time to sale did not influence participants' assessments of relevance, we omit this variable from the model.

FIGURE 3
Structural-Equations Model, Experiment 1



This figure summarizes results from Experiment 1. It illustrates that manipulated source competence, a property related to reliability, significantly influences users' assessments of both the reliability of the measurement and the relevance of current value information. It further demonstrates that users take their assessments of both reliability and relevance into account when determining how much weight to put on the reported information in valuing the firm.

Overall, the model fits the data well. The traditional $\chi2$ test shows a good fit ($\chi2 = 0.99$, $p = 0.32$), as do other standard fit measures.[11] Turning to the path coefficients, the relationship between our manipulated source competence variable and assessed reliability (Link 1) is positive and significant ($p < 0.01$), consistent with a successful manipulation of factors underlying reliability. The relationship between competence of the valuation source and assessed relevance (Link 2) is positive and significant ($p < 0.01$), consistent with H1. Finally, both assessed reliability (Link 3) and assessed relevance (Link 4) are, in turn, positively associated with the valuation effect ($p < 0.05$ and $p < 0.01$, respectively). Both of the indirect effects of source competence on valuation (through assessed reliability and through assessed relevance) are significant ($p < 0.01$) by the product of Z-Scores test (Holbert and Stephenson 2003), indicating that both paths are meaningful. These results support H2.

These Experiment 1 results support our theory that variations in source competence cause users to assess differences in reliability, as one would expect. Moreover, our results also support our theory by showing that reliability has an additional effect on relevance judgments. Both assessed reliability and assessed relevance, in turn, affect valuation judgments (i.e., their joint influence is decision useful). These results strongly suggest that properties underlying reliability have too much emphasis in valuation.

IV. EXPERIMENT 2

Overview

Experiment 1 provides evidence supporting our theory that variations in a property underlying reliability (i.e., source competence) influence the assessed relevance of current value information. Additionally, Experiment 1 supports the idea that source competence, as a property of reliability, influences users' valuation judgments by two distinct paths—through both assessed reliability and assessed relevance.

In our second experiment, we test whether our theory holds for a second property related to the reliability of a measurement—whether the measurement arises from a market transaction of a comparable item or from a model. We also attempt a stronger manipulation of factors underlying relevance in Experiment 2, to allow a test of the directionality of the relationship between relevance and reliability. The use of different manipulations of the underlying properties of reliability and relevance is also helpful in demonstrating the generalizability of our theory.

Participants, Design, and Variables

Ninety-nine M.B.A. students from a *BusinessWeek* top-25 school volunteered to participate in Experiment 2 in return for a small fixed payment. The participants had an average of 5.0 years of work experience. Seventy-two percent of participants had previously made investments in common stocks, and 97 percent either had invested or planned to invest in common stocks in the future. Participants had taken an average of 4.7 finance and 3.0 accounting classes. We paid participants \$10 for their participation in this and an unrelated study.[12]

---

[11] The Comparative Fit Index, a measure of the proportion of improvement of the fit of our model to the null model, is 1.00, which is above the generally accepted minimum value of 0.95 (Byrne 2001). The Incremental Fit Index (1.00) is above the recommended minimum of 0.95 (Byrne 2001), and the Root Mean Square Error of Approximation (0.00) is below the recommended maximum of 0.01.

[12] Participants completed the unrelated study before participating in Experiment 2. We counterbalanced conditions of the other study with those of our experiments, alleviating the potential for carryover effects. Statistical tests reveal no systematic carryover effects.

As in Experiment 1, we asked participants to assume the role of a potential investor in a fictitious company. All were told that the company had acquired a plot of land for $41 million two years ago that was recently estimated to have a current value of $53 million. Similar to the first experiment, Experiment 2 makes use of a 2 × 2 full-factorial, between-participants design. We manipulated underlying properties of both the reliability of the current value measurement and the relevance of current value information. Specifically, we manipulated the valuation method used in deriving the land's current value as based on the market price of a comparable asset (e.g., Level 2 of SFAS 157 valuation hierarchy) or estimated from a model (e.g., Level 3). We did not use SFAS 157 terminology in our materials. The two levels correspond to high and low reliability and are referred to as "comparable" and "model," respectively.[13]

We manipulated the intended use of the asset as an underlying property of relevance.[14] At one level ("sell," corresponding to high relevance), the land is owned by a real estate development firm that holds the land for development and sale. At the other level ("use," corresponding to low relevance), the land is owned by a cosmetics manufacturing firm that holds it for purposes of building its own factory. Intended use incorporates time to sale (i.e., presumably the real estate developer will sell the land first, making its fair value potentially more timely) and separability of the asset from other operations (i.e., the separate value of land to be developed and sold is likely more relevant for the assigned valuation task than is the fair value of land that is part of productive capacity, because the latter would be valued "in use" rather than separately) (SFAS 157). Figure 4 illustrates the manipulations.

After receiving the information described above, participants made four assessments. The first three response measures are identical to the first three measures captured in Experiment 1 (i.e., relevance of the current value information [i.e., the construct], reliability of the number assigned to the land's current value [i.e., the measurement], and valuation effect of the information). Participants also assessed management trustworthiness using a 101-point scale ranging from "not at all trustworthy" (0) to "extremely trustworthy" (100).

Results

Preliminary Tests

As anticipated, reliability was assessed higher by those in the comparable conditions (mean of 64.06) as compared with those in the model conditions (mean of 42.60) ($F_{1,95} = 31.76$, $p < 0.01$). The manipulation of intended use (i.e., relevance) did not influence reliability judgments (not tabulated), a point we return to in later tests for this second experiment. That is, assessed reliability was not statistically different in the sell and use conditions (means 54.14 and 52.29, respectively, $F_{1,95} = 0.19$, $p = 0.67$). Further, the interaction of intended use and valuation method was not significant ($F_{1,95} = 0.21$, $p = 0.65$).[15]

---

[13] Following the argument of Song et al. (2010), this manipulation is a joint manipulation of bias and potential for error. Specifically, those authors contend that investors' downward valuation adjustment for reported Level 3 fair values is likely due to two factors: (1) a downward adjustment to the cash flow effect of the item due to potential bias on the part of management, and (2) an upward adjustment to the discount rate applied to the reported amount due to uncertainty or noise in the fair value estimate.

[14] The issue of whether intended use *should* normatively affect relevance judgments is subject to debate. For the purposes of this study, however, it is not necessary to establish whether individuals should or should not normatively react to intended use, but only that it will influence assessments of relevance and is unrelated to reliability.

[15] If users expected the real estate company to more reliably estimate the value of the land than the cosmetics company, then our intended use manipulation could be viewed as a manipulation of both relevance and reliability. However, the lack of any significant effects of intended use on judged reliability rules out this possibility.

FIGURE 4
Example of Materials Used in Experiment 2

Panel A: Sell, Model Condition

In Year 1, WRSwann Co. purchased a plot of land for $41,000,000. WRSwann Co. is a real estate development firm that routinely purchases, develops, and sells land. The land is ideally suited for development, given its proximity to dense, high-income neighborhoods and transportation.

In Year 3, WRSwann Co. places a current value on the land in the amount of $53,000,000.

This current value number was generated internally by company management. Management based the current value number on an internally developed model (i.e., marked-to-model). There are no comparable plots of land upon which to determine the current value; hence, management used a model to determine the value.

Year 1 Value	Year 3 Value
$41,000,000	$53,000,000

Panel B: Use, Comparable Condition

In Year 1, WRSwann Co. purchased a plot of land for $41,000,000. WRSwann Co. is a cosmetics manufacturing company that plans to build its factory on the land. The land is ideally suited for the factory, given its proximity to an appropriate workforce and an already established distribution center.

In Year 3, WRSwann Co. places a current value on the land in the amount of $53,000,000.

This current value number was generated by an external valuation firm. This external valuation firm based the current value number on a comparable plot of land (i.e., adjacent to the one purchased by WRSwann, same size, and same location desirability). This comparable plot of land was recently sold.

Year 1 Value	Year 3 Value
$41,000,000	$53,000,000

An ANOVA model for participants' ratings of management's trustworthiness (not tabulated) revealed a significant main effect of valuation method ($F_{1,95} = 13.83$, $p < 0.01$). Participants in the comparable conditions rated management trustworthiness significantly higher than did those in the model conditions (58.78 for comparable versus 49.52 for model). Neither intended use ($F_{1,95} = 0.01$, $p = 0.92$) nor the interaction of intended use and valuation method ($F_{1,95} = 1.22$, $p = 0.27$) is significant in the model. Collectively, these results indicate that our manipulation of the valuation method successfully influenced participants' views of the reliability of the asset's reported value.

Tests of Hypotheses

Descriptive (inferential) statistics for participants' assessments of relevance are presented in Panel A (Panel B) of Table 2. The ANOVA reveals a significant main effect of valuation method ($F_{1,95} = 8.44$; $p < 0.01$) such that participants in the comparable conditions judged the relevance of current value information (mean of 68.49) significantly higher than did those in the model conditions (mean of 53.94). Thus, underlying factors (e.g., error and bias) of the reliability of a current value measurement influence financial statement users' assessments of the relevance of current value information, supporting H1. Consistent with the findings from Experiment 1, this supports our theory that users base their evaluations of relevance on the more accessible reliability attribute. Support for participants' reliance on attribute substitution is also indicated by a positive and highly significant correlation of assessed reliability and relevance ($r = 0.48$, $p < 0.01$).

The ANOVA for relevance also reveals a significant main effect of intended use ($F_{1,95} = 4.97$; $p = 0.03$) and an insignificant interaction of valuation method and intended use ($F_{1,95} = 0.19$; $p =$

Residual	95	609			95	1264		

Participants assessed the relevance of the current value information to their overall evaluation of the firm. We manipulated whether the current value was derived from a market transaction for a similar asset (e.g., level 2 of SFAS 157 valuation hierarchy) or from a model (e.g., level 3). We also manipulated the intended use of the asset as either "use" (the land is held for purposes of building the owner's factory) or "sell" (the land is held for development and sale). The dependent measures are described in the notes to Table 1.

0.67). The significant effect of intended use arises from participants in the sell conditions assessing higher relevance for current value information (mean of 66.68) than participants in the use conditions (mean of 55.49). This result indicates that we successfully manipulated participants' views of relevance independent of reliability.

The fact that our manipulation of intended use significantly influenced assessed relevance without affecting assessed reliability provides evidence in support of the unidirectional relationship between relevance and reliability. While factors underlying reliability affect both assessed reliability and assessed relevance, factors underlying relevance influence only assessed relevance. To further test the direct effect of these underlying properties on users' assessments of reliability and relevance as well as the indirect effect of these properties on users' valuation decisions, we employ structural equations analysis.

As shown in Table 2, an ANOVA model for participants' valuation judgments reveals significant main effects of intended use and valuation method. Valuation judgments were more positive when the current value was based on a comparable market transaction (mean of 40.08) versus a model (mean of 19.12) ($F_{1,95} = 8.18$, $p < 0.01$). They also were more positive when the company intended to develop and sell the asset (mean of 36.32) than when they were intending to use the asset in operations (mean of 22.17) ($F_{1,95} = 3.71$, $p = 0.06$). There was no evidence of an interaction of these two variables ($F_{1,95} = 0.61$, $p = 0.44$).

For H2, recall that we predict that factors underlying the reliability of a current value measurement will influence valuation via two paths—through users' assessments of the reliability of the measurement and through their assessments of relevance. Thus, we expect that the valuation method (i.e., comparable versus model) will influence both assessed reliability and assessed relevance and that each will separately influence valuation. We test H2 using a structural-equations model, as presented in Figure 5.

The model is similar to that tested in Experiment 1, except that we include in the model the intended use variable, which significantly influenced participants' relevance judgments. Before exploring the links in the model, we first test the overall fit using various indices. The traditional $\chi 2$ test shows a good fit ($\chi 2 = 1.92$, $p = 0.59$), as do other standard fit measures.[16] Thus, our model describes well the relations in the data.

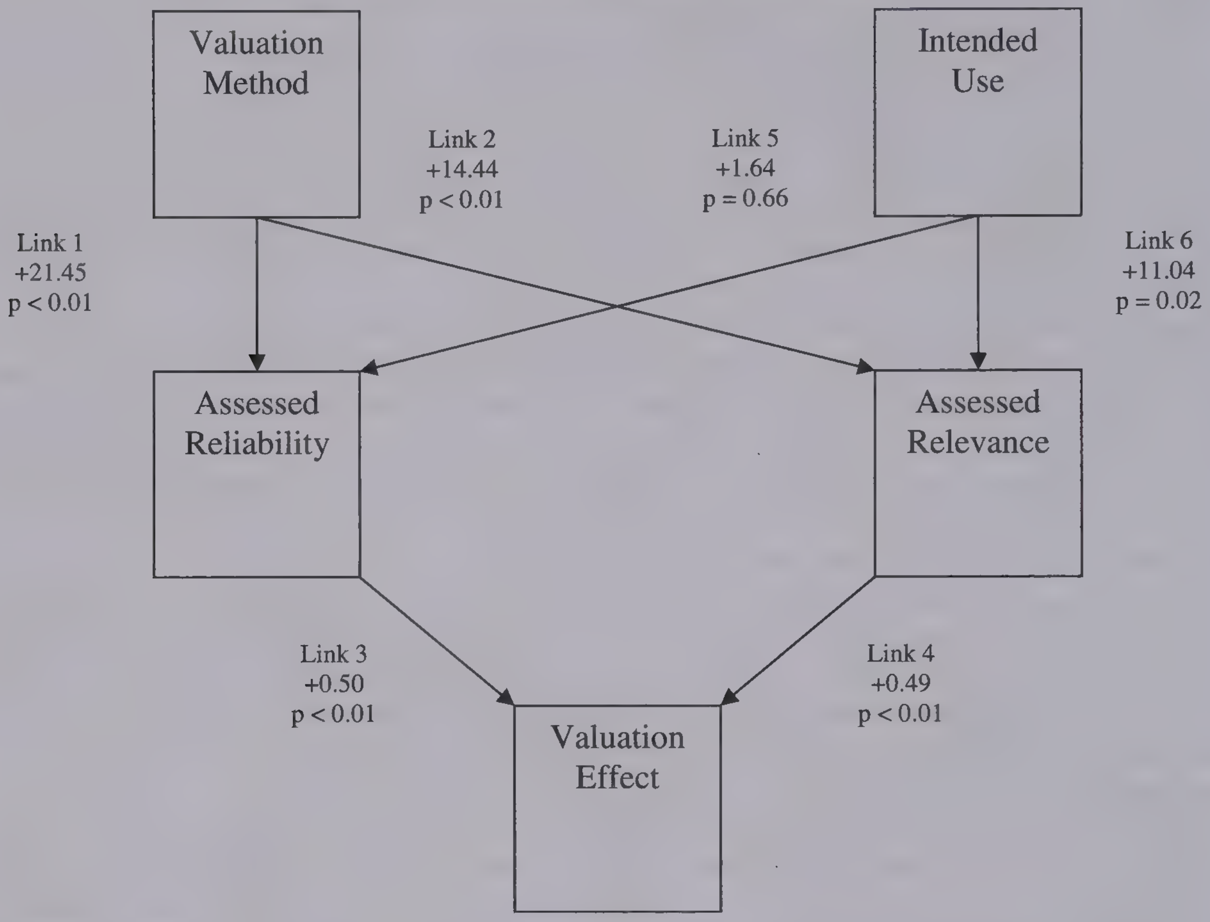
Figure 5 presents path coefficients and statistical significance. The relationship between valuation method, with model coded as 0 and comparable coded as 1, and assessed reliability (Link 1) is positive and significant ($p < 0.01$), consistent with a successful manipulation of factors underlying reliability. Consistent with H1, the relationship between valuation method and assessed relevance (Link 2) is also positive and significant ($p < 0.01$). Further, both assessed reliability (Link 3, $p < 0.01$) and assessed relevance (Link 4, $p < 0.01$) are significantly associated with valuation, indicating that both influence decision usefulness. Finally, both indirect effects of valuation method on valuation—one through assessed reliability and the other through assessed relevance—are significant ($p < 0.01$, product of Z-scores test), indicating there are two distinct and meaningful paths by which factors underlying reliability affect valuation. These findings support H2.

Further analysis of our results shows that while properties underlying reliability influence relevance judgments, the reverse is not true. That is, properties associated with relevance do not influence reliability judgments. To see this, turn to our manipulation of intended use of the asset (with "use" coded as 0 and "sell" coded as 1). There, we see a significant positive relationship with assessed relevance (Link 6, $p = 0.02$), indicating a successful manipulation of factors underlying

---

[16] The Comparative Fit Index is 1.00, which is above the generally accepted minimum value of 0.95 (Byrne 2001); the Incremental Fit Index (1.01) is above the recommended minimum of 0.95 (Byrne 2001); and the Root Mean Square Error of Approximation is 0.00, which is below the recommended maximum of 0.01.

FIGURE 5
Structural-Equations Model, Experiment 2



This figure summarizes results from Experiment 2. It illustrates that manipulated valuation method (i.e., comparable transaction versus model), a property related to reliability, significantly influences users' assessments of both the reliability of the measurement and the relevance of current value information. It demonstrates the directionality of this "confusion" between reliability and relevance by showing that the assets' intended use (use as a factory site versus held for sale), a determinant of relevance, significantly influences assessed relevance but does not influence assessed reliability. It further demonstrates that users take their assessments of both reliability and relevance into account when determining how much weight to put on the reported information in valuing the firm.

relevance. Most pertinent to our purposes, the link between the intended use variable and assessed reliability is insignificant (Link 5, $p = 0.66$), indicating that the reliability-relevance relationship is strictly unidirectional, as we posit.

An alternative specification of this model includes a link from assessed reliability to assessed relevance instead of the link from valuation method to assessed relevance. This model is computationally equivalent to the model we test for Experiments 1 and 2, and so fit measures are identical. Both our model and the alternative model are consistent with our theory, as they imply that evaluations of relevance rely on the more accessible reliability attribute.

Ruling Out an Alternative Substitute Attribute

Our theory predicts that users have difficulty assessing relevance, and so will substitute the reliability attribute for relevance. We believe reliability to be the most likely candidate for attribute substitution. Reliability is a basic property of measurement that prior research indicates individuals assess relatively accurately, and thus it is highly accessible. Results of our experiments support this theory. However, an alternative possibility is that users substitute decision usefulness for relevance. That is, they may use the label "relevance" to capture the idea of decision usefulness, which includes the effects of both relevance and reliability (FASB 1980, 2010). We conduct additional analyses to rule out this possibility.

First, recall that the path analysis in Experiment 2 shows that manipulations of properties underlying relevance and reliability affect participants' valuation judgments.[17] If participants used the relevance label to capture decision usefulness, then we would observe the assessed relevance measure capturing *all* effects of factors underlying both relevance and reliability on our valuation dependent measure. However, our analysis does not support this result. Instead, as seen in Figure 5 (Link 3), assessed reliability has a significant effect on valuation above and beyond the impact of assessed relevance on valuation. As a further test of this same idea, we estimated a model identical to that in Figure 5, except that we omitted Link 3. This model also tests the idea that judged relevance is used as a proxy for decision usefulness. The alternative model is a poor fit to the data, and a nested model test shows that our model fits the data significantly better ($\chi_1{}^2 = 8.482$, $p < 0.01$). These results indicate that our participants did not consider relevance as a substitute for decision usefulness.

V. ROBUSTNESS TESTS

We conducted two additional experiments to test the robustness of the findings from our main experiments. First, to determine whether these results hold even if participants are provided with the FASB's definitions of relevance and reliability, we undertook a third experiment with the same design as Experiment 2 with a separate group of 94 participants from a similar population (M.B.A. students with mean work experience of 8.4 years, average of 3.5 finance and 3.1 accounting classes, 81 percent had previously invested in common stocks, and 89 percent planned to do so). Our results are similar to those reported for Experiments 1 and 2. That is, the manipulation of valuation method (i.e., market price of a comparable asset versus model estimate) influenced participants' assessments of relevance ($F_{1,90} = 7.38$; $p < 0.01$) despite the prominent display of FASB's definitions in the materials. Participants assessed relevance as higher in the comparable conditions (i.e., high reliability; mean of 75.60) than in the model conditions (i.e., low reliability; mean of 62.95).

Second, to ensure that participants interpreted the relevance question as referring to the general construct of current value information (versus a specific measurement), we conducted a fourth experiment based on Experiment 2 with a separate group of 47 M.B.A. student participants (mean work experience of 8.4 years, average of 3.8 finance and 3.6 accounting classes, 72 percent had previously invested in common stocks and 91 percent planned to do so). We used the model and comparable conditions for the high relevance condition (i.e., sell) from Experiment 2, with one change. We asked about the relevance of "current value information" rather than "*the* current value information." Again, we replicated our Experiment 2 findings. Assessments of relevance were significantly higher in the comparable condition than in the model condition (68.5 versus 50.1, $F_{1,45} = 6.68$; $p = 0.01$).

VI. CONCLUSIONS

In this study, we experimentally investigate the hypothesis that factors underlying the reliability of a fair value measurement influence financial statement users' assessments of the relevance of fair value. Such an assessment is inconsistent with the qualities of relevance and reliability being independent constructs. We base our tests on attribute substitution theory, which predicts that this relationship arises because financial statement users can access more readily the reliability attribute than the relevance attribute. Thus, when asked to assess relevance, financial statement users substitute an easier question—one about reliability—in forming a response. Our results support our hypothesis, revealing that factors underlying the reliability of a fair value measurement—namely, the competence of the source of the measurement (Experiment 1) and whether the measurement is based on a market transaction for a comparable item or a model calculation (Experiment 2)—strongly influence users' assessments of the relevance of fair value information. Attribute substitution further predicts that this relationship will be unidirectional. That is, when asked to assess reliability, financial statement users will do so rather than substitute the relevance attribute. Our results also support this assertion.

---

[17] We did not conduct this test for Experiment 1 as it is less meaningful there, because the manipulation of time to sale (i.e., relevance) showed an insignificant main effect on our dependent measures.

We also demonstrate that factors underlying the reliability of a measurement affect users' valuation judgments through two paths: (1) their influence on assessed reliability, and (2) their influence on assessed relevance. Both of these paths are highly significant in our experiments. While these results are highly suggestive of an over-weighting of factors underlying reliability in valuation, without a normative benchmark we cannot be certain that this is occurring. Future research can draw on our insights to further explore this issue.

Future research also could examine boundary conditions on attribute substitution for relevance and reliability. That is, does what we observed in a fair value context hold in other financial reporting situations? In many financial reporting contexts, users receive a measurement possessing a given level of reliability and relevance, and relevance is typically more difficult to assess than reliability. Thus, we expect the results we observed to obtain generally in these contexts. However, we caution readers that our results may not generalize to other financial reporting contexts in which relevance is made particularly salient, and is therefore more accessible, or in contexts in which reliability is particularly difficult to assess. In such cases, attribution substitution either would not occur or would take a different form than we observe.

Future research could further explore the extent to which financial statement users are aware of the attribution substitution. Recall that attribute substitution theory indicates that individuals are generally unaware of the substitution they are making. Although we did not design our tests to investigate the role of awareness, we nevertheless report results that are consistent with theory, with no obvious alternative explanation for the observed effects. Future research could address the awareness issue by employing, for example, verbal protocol analysis to determine if users are aware of their use of factors underlying reliability when assessing relevance. If this research shows that individuals are aware of the substitution, additional research also could investigate whether participants purposefully use reliability information when judging relevance. We believe such intent is unlikely, since the substitution effect persists when we gave participants definitions of the terms. The fact that this substitution occurs is important regardless of awareness or intentionality, given that it is at odds with a view of relevance and reliability as independent constructs.

This study has important implications for standard setters, firm management, and financial statement users. First and foremost, our findings suggest that financial statement users are likely to make errors in judgments. Because these errors are apparently driven by the difficulties of assessing relevance and the resulting use of a heuristic, training may not be effective in correcting the problem. For example, even individuals with extensive statistical training ignore base rates and rely on representativeness when making intuitive judgments (Tversky and Kahneman 1974, 1130).

The phenomena that we document are also likely to interfere with standard setters' efforts to expand the use of fair value in financial reports. Observers focusing on unreliable fair value measurements have argued that fair values are irrelevant, as a result. We note that this is akin to asserting that the outdoor temperature is not relevant to one's decision whether to wear an overcoat simply because the thermometer at hand is unreliable. A better understanding of the underlying issue—users' inability to assess relevance independently from reliability—indicates that standard setters may wish to focus on addressing how to communicate the relevance of the particular constructs separate from their efforts to improve the reliability of their measurements.

Investor Sentiment and Stock Market Response to Earnings News

G. Mujtaba Mian

ABSTRACT: We examine whether market-wide investor sentiment influences the stock price sensitivity to firm-specific earnings news. Using the recently developed measure of investor sentiment by Baker and Wurgler (2006), we find that the stock price sensitivity to good earnings news is higher during high sentiment periods than during periods of low sentiment, whereas the stock price sensitivity to bad earnings news is higher during periods of low sentiment than during periods of high sentiment. This influence of sentiment is especially pronounced for the earnings news of small stocks, young stocks, high volatility stocks, non-dividend-paying stocks, and stocks with extremely high and low market-to-book ratios. Further analysis suggests that the sentiment-driven mispricing of earnings contributes to the general mispricing of stocks due to investor sentiment.

I. INTRODUCTION

Accounting research has long been interested in the valuation implications of corporate earnings. Traditionally, these studies have been couched in an efficient markets framework that postulates that accounting information is efficiently impounded into stock prices by rational agents in well-functioning capital markets (Holthausen and Watts [2001] and Kothari [2001] survey this research). In fact, in many cases, researchers rely on the maintained assumption of the efficient pricing of information and use the change in stock prices around an

information event as a reliable yardstick to quantify the effect of that event on shareholder value. This view precludes any significant role of investors' behavioral biases in shaping their response to accounting information. Developments in the field of behavioral finance, however, are increasingly spurring accounting researchers to question this view (Lee 2001; Daniel 2004; Hirshliefer and Teoh 2003; Hirshliefer and Teoh 2009). Lee (2001), for instance, challenges the traditional assumption that the price adjustment to new information is always rational and instantaneous, and calls for more work that incorporates the findings of behavioral finance into capital market research in accounting to better understand the process by which stock prices incorporate accounting information.

In this paper, we examine the impact of investors' behavioral biases, measured by market sentiment, on the sensitivity of stock prices to earnings surprises (Earnings Response Coefficients [ERCs]). Market sentiment can be broadly defined as the beliefs about future cash flows or discount rates that are not supported by the prevailing fundamentals (Baker and Wurgler 2006). Prior literature on market sentiment has established that (1) reasonable proxies of investor sentiment can be identified, and (2) sentiment has discernible and regular effects on the stock market (Brown and Cliff 2005; Baker and Wurgler 2006; Lemmon and Portniaguina 2006; Kaplanski and Levy 2010). A key finding of this literature is that when sentiment is high, investors' propensity to speculate is high, so they place excessively optimistic valuations on future expected cash flows associated with risky assets such as stocks, either by overestimating the size of the cash flows or by underestimating the risk, leading them to overvalue stocks. The reverse is true for the low sentiment periods, when investors place excessively pessimistic valuations on future expected cash flows, and undervalue stocks.[1] This contemporaneous misvaluation due to sentiment reverses in the future, thereby creating a negative relation between sentiment and future risk-adjusted returns, especially for more speculative stocks.

We extend this misvaluation argument of Baker and Wurgler (2007) to the setting of earnings announcements. We note that an earnings announcement brings with it information about future earnings and cash flows of the firm (Kasznik and McNichols 2002), and the stock price response to the announcement entails investors' valuation of these *incremental* cash flows. Following the argument of the sentiment literature, investors are likely to place optimistic valuations on the incremental cash flows embedded in earnings announcements during periods of high sentiment and pessimistic valuations during periods of low sentiment. For good earnings news, which generally signifies positive incremental cash flows, an optimistic valuation during high sentiment periods and pessimistic valuation during low sentiment periods implies a greater stock price increase during high sentiment periods than during low sentiment periods. For bad news, on the other hand, which generally signifies negative incremental cash flows, an optimistic valuation during high sentiment periods and a pessimistic valuation during low sentiment periods implies a smaller stock price reduction during high sentiment periods than during low sentiment periods. Therefore, in this paper, we test the hypothesis that the ERC of good (bad) earnings news is higher (lower) when sentiment is high than when sentiment is low, leading to a positive (negative) association between the ERC of good (bad) news and investor sentiment.[2]

---

[1] The limits on arbitrage constrain rational traders from forcing the prices back to their fundamental value (Baker and Wurgler 2006, 2007).

[2] While we follow the "top-down" approach of the sentiment literature (see, for example, Baker and Wurgler 2007), and motivate our hypothesis using the broad notion of optimistic and pessimistic valuation by investors during high or low sentiment periods, several specific *individual* biases of investors, which are well-documented in the behavioral finance literature, also produce similar predictions. For instance, Barberis et al. (1998) consider *conservatism* and *representativeness* and show that investors overreact to the new information when it conforms to their prior beliefs and underreact when it contradicts the prior beliefs. Similarly, under *confirmatory bias*, individuals interpret new evidence based on whether the new information conforms or contradicts their prior beliefs (Barberis and Thaler 2003; Hirshliefer 2001).

The primary proxy for investor sentiment in our analysis is the monthly sentiment index developed by Baker and Wurgler (2006). We use the standard event study methodology to compute the three-day abnormal returns around the announcement of earnings as our measure of stock price sensitivity to news. Our results confirm that the stock price sensitivity to good news increases with sentiment, whereas the stock price sensitivity to bad news decreases with sentiment. Consistent with the notion that the incremental cash flows embedded in bad earnings announcements are more uncertain and difficult to value than the incremental cash flows that are embedded in good earnings news, we find that the effect of sentiment on stock price sensitivity is significantly stronger for bad news than for good news. We also validate the prediction in the recent sentiment literature that the effect of sentiment persists over a prolonged period and does not reverse immediately in the short term (Brown and Cliff 2005; Baker and Wurgler 2006). Specifically, we find that the effect of sentiment persists and influences the drift in stock prices in the subsequent 60 days after the earnings announcement.

We also connect the sentiment-related mispricing of earnings to the broader effect of sentiment on prices as delineated by the previous literature. Despite several papers that establish a relation between sentiment and mispricing of stocks (Baker and Wurgler 2006; Lemmon and Portniaguina 2006; Qiu and Welch 2006), the precise channel(s) by which sentiment causes such mispricing is not well understood. Because earnings announcements represent important events that lead to abnormally high trading, especially by small traders,[3] we hypothesize and document that the sentiment-driven misreaction of stock prices to earnings news contributes importantly to the general overpricing (underpricing) of stocks during periods of high (low) sentiment documented in the prior literature. Specifically, in bullish (bearish) times, the market overreacts (underreacts) to good earnings news and underreacts (overreacts) to bad news, and this contributes significantly to the overpricing (underpricing) of stocks during bullish (bearish) times.

The prior literature also argues that the effect of sentiment on the valuation of stocks is not uniform across stocks, and is greater for speculative stocks whose expected cash flows are more uncertain and more difficult to value (Baker and Wurgler 2006; Lemmon and Portniaguina 2006). In our setting, sentiment affects the (mis)pricing of earnings because it induces investors to misvalue the *incremental* cash flows embedded in the earnings announcements. Because the earnings of speculative stocks are often also less persistent (Baginski et al. 1999), it can make the identification and valuation of the associated incremental cash flows harder and more subjective, leading to a greater effect of sentiment in the pricing of the earnings of such stocks. Therefore, we investigate and find that the effect of sentiment on the (mis)pricing of earnings is greater for small, young, volatile, non-dividend-paying, and extremely high- and low-growth stocks than for the corresponding categories of large, mature, stable, high-dividend-paying, and medium-growth stocks, respectively.

An alternative explanation for our results could be that good (bad) news during high (low) sentiment periods has greater inherent information content than good (bad) news during low (high) sentiment periods. The higher ERC of the good (bad) news during high (low) sentiment periods might, therefore, simply reflect the greater information content of the news during such periods. Using the measure of information content of earnings developed by Kasznik and McNichols (2002; hereafter, KM), we find, however, no evidence in support of this information-based story.

We also rule out risk-based explanations for our results for three reasons. First, we compute the abnormal returns after controlling for the known risk measures of size, book-to-market ratio, and momentum. Second, we accumulate the returns over a three-day window and the variation of risk over time is less likely to be an explanation for such a short return accumulation period. Finally, if sentiment captures time-varying discount rates in some way, then the effect for good and bad news should be similar, but we find that the ERC for good news increases, whereas the ERC for bad news decreases with sentiment.

---

[3] Lee (1992) and Battalio and Mendenhall (2005), for example, find that while both large and small traders increase their trading around earnings announcements, small traders do so to a greater extent.

Our key finding is that investors' behavioral biases affect how accounting information is impounded into prices. This casts a doubt on the traditional view that the short-term change in stock price is an unbiased and efficient benchmark for assessing the valuation implication of accounting information. As Lee (2001) notes, if the stock price reaction to accounting information contains both rational and irrational components, then the change in stock price around the announcements of accounting information cannot be used by researchers as the *sole* reliable yardstick to assess the value-relevance of the information. The tests of value-relevance need to be bolstered to include measures of *long-term* accounting, product-market, and stock price performance.

Our paper also helps to advance the literature on investor sentiment in two ways. First, we identify mispricing of earnings as an important channel through which sentiment can cause mispricing of stocks. Second, an alternative explanation for the relation between sentiment and stock returns documented in prior work is that sentiment captures time-varying discount rates in some way. If sentiment just reflected time-varying discount rates, then it should have roughly equal effects on both good and bad news in our setting, but we find that this is not the case, further validating the sentiment proxies developed in the prior literature.

Our paper complements two other concurrent papers on the interplay of accounting information and investor sentiment. Seybert and Yang (2012) show that a significant part of the negative stock returns following high sentiment periods is concentrated around management forecast dates. Their study provides insight into how sentiment-related earnings mispricing is later corrected. Hribar and McInnis (2012) examine whether analyst forecast errors of earnings and earnings growth vary with sentiment. They show that these *ex post* forecast errors seem to explain a sizable fraction of the return patterns in Baker and Wurgler (2006). Our paper is different from these studies in that we examine how sentiment affects the initial pricing of earnings information, and how the reversal of this effect contributes to the relation between sentiment and future returns.

Section II describes our data-selection process and research methodology. Section III reports our main results on the effect of sentiment on stock price sensitivity to earnings news. Section IV provides additional analyses, which suggest that sentiment also influences the post-earnings announcement drift, that large earnings surprises affect the relation between sentiment and future returns, and that the pricing effects of sentiment vary cross-sectionally in a way that is consistent with the underlying theory. We provide robustness checks in Section V and conclude the paper in Section VI.

II. DATA AND RESEARCH DESIGN

Data and Sample Selection

Our sample period is 1972 to 2007 for which we could obtain both the Compustat quarterly earnings data and the Baker-Wurgler investor sentiment index. We identify the earnings announcement dates from Compustat and I/B/E/S by following the procedure outlined in DellaVigna and Pollet (2009). For each earnings announcement, we define a three-day event window centered on the date of the event, and calculate the abnormal return for each day as per the method described in Daniel et al. (1997; hereafter, DGTW). This methodology allows for the differences in expected returns that might be related to size, book-to-market ratio, and past returns. Specifically, we calculate the daily abnormal return by subtracting the return on a portfolio that is similar to the stock in terms of size, book-to-market, and past return momentum. We obtain the daily stock returns data from the Center for Research in Security Prices (CRSP). The daily abnormal returns are summed to compute the cumulative abnormal return for each earnings announcement.

Rather than using analyst forecasts, we use seasonally differenced earnings changes as a proxy for unexpected earnings associated with each earnings announcement for three reasons. First, the random walk model of expected earnings allows us to use a longer sample period of 1972–2007, whereas the analyst forecast data are only available starting from 1985. A long sample period gives more power to our tests to explore the role of investor sentiment, which changes slowly over time, and ensures that one or two extreme episodes such as the bull market of the late 1990s do not drive our results. Second, analyst forecasts for quarterly earnings are missing in I/B/E/S for small companies.[4] These, however, are precisely the companies that Baker and Wurgler (2006) argue are more prone to sentiment, and are the most suitable for studying the importance of sentiment in financial markets. Large firms, in contrast, may not be affected by sentiment, or may even be affected in the opposite direction as investors perceive these as safe havens (i.e., blue chip investments) in times of low sentiment (Baker and Wurgler 2007). Finally, Battalio and Mendenhall (2005), among others, show that less-sophisticated small investors rely on time-series forecasts as their expectations of earnings. Since small investors are commonly perceived to be more prone to sentiment (Baker and Wurgler 2007; Kumar and Lee 2006), earnings surprises based on time-series forecasts are more suited to study how sentiment drives investor reaction to earnings news. Nevertheless, in a later section, we report the results for earnings surprises that are computed relative to analyst forecasts.

Following Livnat and Mendenhall (2006), we calculate the unexpected earning, *UE*, which represents the news component associated with the earnings announcement, as follows:

$$UE_{iq} = \frac{Earnings_{iq} - Earnings_{iq-4}}{P_{iq}}. \tag{1}$$

$Earnings_{iq}$ is the primary earnings per share of firm i for quarter q, and P_{iq} is the price per share at the end of quarter q. As in Livnat and Mendenhall (2006), we exclude "special items" in computing the earnings. We take into account stock splits and to mitigate the impact of the erroneous and extreme observations, we trim the distribution of the unexpected earnings at 1 percent and 99 percent. Finally, because prior research shows that the earnings response coefficients are essentially zero for negative earnings (Hayn 1995; Lipe et al. 1998), we delete observations with negative earnings.[5]

In much of our analysis, we split earnings news into good news and bad news because our prediction as to whether earnings are overpriced or underpriced during a certain state of sentiment depends on whether the news is good or bad. We first create two indicator variables, *Up* and *Down*, where *Up* (*Down*) equals 1 if the unexpected earnings is positive (negative), and 0 otherwise. We then multiply *UE* by these indicator variables to yield *UEUp* and *UEDown*, which are our measures of good and bad earnings news, respectively.

To measure investor sentiment, we employ the sentiment index developed by Baker and Wurgler (2006, 2007), which is available on a monthly basis.[6] The index is based on six measures of investor sentiment: closed-end fund discount, NYSE share turnover, number of IPOs, first day returns on IPOs, share of equity issues in total debt and equity issues, and dividend premium (the log difference of the average market-to-book ratios of payers and non-payers). Each of these six measures is first regressed on macroeconomic variables that capture variations in the business cycle, including growth in industrial production index, consumer durables, consumer nondurables, and consumer services. The overall sentiment index is the first principal component of the residuals from the preceding six regressions. The index is standardized to yield a mean of 0 and a standard deviation of 1. Baker and Wurgler (2006, 2007) demonstrate that this sentiment index lines up well with anecdotal accounts of investor exuberance and panic. They also validate the index by providing evidence of the link between the index and the time-series variation in the cross-sectional returns that cannot be explained by rational risk-based models.

---

[4] Prior studies have recognized the large-firm bias of I/B/E/S data. For instance, Hong et al. (2000), who examine *annual* earnings forecasts, find that analyst forecasts are missing in some years of their sample for about 82 percent of the stocks that fall in the lowest size quintile. The quarterly earnings forecasts in I/B/E/S are sparser than the annual forecasts. For our sample, we find that in the mid-1980s only 5 to 10 percent of the CRSP stocks in the lowest size quintile have quarterly earnings forecasts available in I/B/E/S.

[5] Nevertheless, in Section V we report the results of our analysis for the subsample of loss firms.

[6] At the time of our study, the sentiment data were available through the end of 2007. We thank Jeffrey Wurgler for making available the data on his website (http://pages.stern.nyu.edu/~jwurgler/).

Regression Specification

We measure stock market sensitivity to earnings news by the elasticity of stock prices to unexpected earnings, or ERC, at announcement dates. Our primary hypothesis is that the ERC of good news is higher during periods of high sentiment, whereas the ERC of bad news is higher during periods of low sentiment. Investors are likely to place optimistic valuations on the incremental cash flows embedded in earnings announcements during periods of high sentiment and pessimistic valuations during periods of low sentiment. For good earnings news, an optimistic (pessimistic) valuation during high (low) sentiment periods implies a positive relation between the ERC and investor sentiment. For bad earnings news, an optimistic (pessimistic) valuation during high (low) sentiment periods implies a negative relation between the ERC and investor sentiment.

To test our hypothesis, we estimate the following regression model:

$$\begin{aligned} RET_{it} = {} & \alpha_0 + \alpha_1 Down_{it} + \beta_0 UEUp_{it} + \beta_1 UEUp_{it} \times Sent_{t-1} + \gamma_0 UEDown_{it} \\ & + \gamma_1 UEDown_{it} \times Sent_{t-1} + \beta_2 NonlUp_{it} + \beta_3 UEUp_{it} \times MktPE_{t-1} + \gamma_2 NonlDown_{it} \\ & + \gamma_3 UEDown_{it} \times MktPE_{t-1} + \varepsilon_{it}. \end{aligned} \tag{2}$$

RET_{it} is the cumulative abnormal return for firm i during the earnings announcement event window from day -1 to $+1$ centered on the earnings announcement date in calendar month t. Note that the cumulative abnormal returns are free of the general effect that sentiment has on similar non-announcing stocks since these returns are computed after subtracting the returns on a portfolio of stocks that are similar in size, book-to-market ratio, and past return momentum. Therefore, the abnormal returns represent the differential impact sentiment has on the announcing stocks relative to that of the non-announcing stocks. Because *UEUp* and *UEDown* depict good and bad news separately, the specification in Equation (2) permits the coefficient for *UE* to be different, conditional on the sign of the earnings surprise. We include the indicator variable *Down* as a stand-alone variable to account for the difference in the intercepts of good and bad earnings news (Bartov et al. 2002). Due to the cross-correlation in the returns of announcing firms, our significance tests for Equation (2) are based on the standard errors that are clustered by calendar month.

We multiply the earnings surprise announced in month t with the sentiment at the end of month t–1 to create the interaction variable, $UEUp \times Sent$. This allows us to test whether the ERC of good earnings news varies with the prevailing investor sentiment. If investors are swayed by the prevailing sentiment in their response to earnings news, we expect the coefficient of this interaction term, β_1, to be *positive*, indicating that the market reacts more to good news when sentiment is high. Similarly, we create the interaction variable, $UEDown \times Sent$, to test whether the ERC of bad earnings news varies with sentiment. We expect the coefficient of this interaction term, γ_1, to be *negative*, indicating that the market reacts less to bad news when sentiment is high.

The model includes control variables for nonlinearity in the ERC that has been documented by prior literature (Freeman and Tse 1992). Since the incidence of large earnings surprises, which cause nonlinearity in the ERC, could potentially vary with sentiment, we account for this possibility in our analysis. Specifically, we use two control variables, *NonlUp*, which is the square of *UEUp*, and *NonlDown*, which is the square of *UEDown* multiplied by −1.

We also control for the relative market price-to-earnings multiple based on the results documented by Conrad et al. (2002). We compute the relative market price-to-earnings ratio (*MktPE*) and add the interaction terms $UEUp \times MktPE$ and $UEDown \times MktPE$ in Equation (2) as additional control variables. We follow Conrad et al. (2002) and compute *MktPE* as the ratio of the market price-to-earnings ratio in the month prior to the month of the earnings announcement to the average market-price-to-earnings ratio in the preceding 12 months. We use all the stocks in the merged CRSP-Compustat database to construct the price-to-earnings ratio of the market for a month. We first compute the price-to-earnings ratio for each stock by dividing the market price of the stock with the most recent annual earnings, and then take the value weighted average[7] of the individual firm ratios to obtain the overall market price-to-earnings ratio.[8]

Controlling for the Information Content of Earnings Surprises

The positive earnings surprises that appear during high sentiment periods could indicate higher growth in future earnings than the positive earnings surprises that appear during low sentiment periods. This could also yield higher ERCs for the positive earnings surprises during high sentiment periods. Correspondingly, if the negative earnings surprises announced in low sentiment periods imply a greater drop in future earnings than the negative surprises announced during high sentiment periods, stock prices should rationally respond more to negative earnings surprises during the low sentiment periods. Investor sentiment would then have nothing to do with the differential response of stock prices to good and bad earnings news across different periods.

To test for this possibility, we draw on the methodology in Kasznik and McNichols (2002) to examine how the estimates of the information content of good and bad earnings news vary with sentiment.[9] Specifically, we estimate the following equation:

$$\begin{aligned} Perf_{iq+1} = {} & \alpha_0 + \alpha_1 E_{iq-3} + \beta_0 UEUp_{iq} + \beta_1 UEUp_{iq} \times Sent + \gamma_0 UEDown_{iq} \\ & + \gamma_1 UEDown_{iq} \times Sent + \varepsilon_{iq+1}. \end{aligned} \tag{3}$$

The subscript q in Equation (3) represents the fiscal quarter whose earnings are announced in month t. We drop the month subscript t from Equation (3) to simplify the notation. $Perf_{iq+1}$ is the earnings for firm i one quarter ahead (E_{iq+1}). E_{iq-3} is the earnings three quarters earlier, and is used in the model as the proxy for expected earnings in quarter q+1, which would be announced later. $UEUp_{iq}$ and $UEDown_{iq}$ represent the earnings news for firm i for quarter q. The coefficients β_0 and γ_0 in Equation (3) represent the estimates of the information content of the good and bad earnings news, respectively, for future earnings when sentiment is zero. If good news has higher information content for future earnings during high sentiment periods compared with low sentiment periods, then β_1 should be positive. Similarly, if bad news has higher information content for future earnings during low sentiment periods than high sentiment periods, then γ_1 should be negative. However, if

---

[7] Our results remain robust when we use equal weighting instead.

[8] We note that Conrad et al. (2002) employ the consensus analyst forecast for next year's earnings as the denominator in computing the PE ratios for individual firms. Since analyst forecasts are not available for the earlier period of our sample and we use past earnings as proxy for expected earnings in the rest of our analysis, we therefore divide price by the most recent annual earnings to compute the PE ratio for a firm. Nevertheless, we confirm the robustness of our results for the sub-period 1985–2007, for which analyst forecasts are available, by computing the relative market PE exactly as in Conrad et al. (2002).

[9] We thank the referee for suggesting the Kasznik and McNichols (2002) methodology to test for the informativeness of earnings news.

β_1 and γ_1 are insignificant or of opposite signs, then the differential information content of news across sentiment periods is unlikely to be an alternative explanation for our results.

We also re-estimate Equation (3) after replacing the next-quarter *earnings* as the dependent variable with the next-quarter *cash flows*. This yields an alternative measure of the information content of current-period's earnings news in terms of its implications for future cash flows (CFO_{iq+1}) rather than for future earnings. In this alternate specification, we also include the cash flows three quarters back, CFO_{q-3}, as an additional explanatory variable that depicts the time-series expectation for the future cash flows.

Summary Statistics

Our sample includes 392,212 earnings announcements over the period 1972–2007 for which we could compute the earnings surprises as well as the DGTW risk-adjusted cumulative abnormal returns around the earnings announcement dates. In Table 1, we report the summary statistics of our key variables for the overall sample in Columns (2) through (5). The abnormal announcement and post-announcement returns, $CAR_{(-1\ \text{to}\ +1)}$ and $CAR_{(+2\ \text{to}\ +60)}$, respectively, have both been winsorized at 1 percent and 99 percent of the respective distribution to mitigate the impact of outliers. The mean of the three-day abnormal announcement return is 0.55 percent, which represents the average response to positive, negative, and no-news surprises. The range of these abnormal returns is from −17.89 percent to +21.80 percent. In untabulated analysis, when we estimate the *CAR*s separately for the positive and negative earnings news, the respective *CAR*s are 1.26 percent (t-statistic = 51.75) and −0.89 percent (t-statistic = −30.08), respectively, indicating that stock prices move in the same direction as the sign of the seasonally differenced earnings surprises. The post-announcement return, $CAR_{(+2\ \text{to}\ +60)}$, has a similar mean but a significantly greater standard deviation, which is expected as the post-announcement returns are measured over a significantly longer time period of around 60 trading days. The positive mean of 0.004 for earnings surprise, *UE*, indicates that the earnings news has, on average, been positive. However, when we divide the sample into positive and negative earnings surprises, we note that the mean magnitude of the two sub-groups, $UE[>0]$ and $UE[<0]$, is about the same at 0.012, suggesting that the overall positive mean of *UE* is due to the greater preponderance of positive news in our sample. This is further confirmed in the last two rows of Table 1 where we report that about two-thirds of the earnings announcements in our sample represent positive news, whereas about one-third represent negative news, consistent with our excluding loss firms from our sample. The Baker-Wurgler Sentiment Index ranges from −2.39 to 2.54 during our sample, with a mean close to zero.

We also divide our total sample into three sub-groups based on the estimate of the sentiment at the beginning of the announcement month, and report summary statistics separately for each sub-group in Columns (6) through (11). High (low) sentiment periods are those when sentiment is equal to or greater (less) than 0.5 (−0.5). The medium sentiment periods include the remaining months when sentiment is between −0.5 and 0.5. Differences in the means across high and low sentiment periods are reported in Column (12) and the associated t-statistics are reported in the last column. These are based on the standard errors that are clustered by month.

The average abnormal announcement and post-announcement returns, $CAR_{(-1\ to\ +1)}$ and $CAR_{(+2\ \text{to}\ +60)}$, respectively, are both higher during high sentiment periods. This provides initial support to our hypothesis that the stock price response to earnings news is swayed in the direction of the prevailing sentiment. Furthermore, no monotonic variation in earnings surprise, *UE*, across the high, medium, and low sentiment periods is apparent. However, the mean *UE* seems to be greater during low sentiment than during high sentiment periods. A break-up of the *UE* into positive $UE[>0]$ and negative $UE[<0]$ indicates that the magnitudes of both the positive and negative earnings surprise are larger during low sentiment periods than during high sentiment periods.

*, **, *** Indicate statistical significance at 10 percent, 5 percent, and 1 percent, respectively.

This table reports the summary statistics for the various variables in our sample. The overall sample consists of 392,212 quarterly earnings announcements of firms over the period 1972–2007. Columns (6) through (11) report summary statistics for the three sub-periods of high, medium, and low sentiment. The sub-periods are defined based on the value of the Baker-Wurgler Sentiment Index at the beginning of the announcement month. The high (low) sentiment periods are those when sentiment is equal to or greater (less) than 0.5 (−0.5). The medium sentiment periods include those when sentiment is between 0.5 and −0.5. Column (12) reports the difference in the means across high and low sentiment periods. The t-statistics reported in Column (13) are based on standard errors clustered by month.

Variable Definitions:

$RET_{-1,+1}$ = three-day cumulative abnormal return centered on the date of the earnings announcement;

$RET_{+2,+60}$ = cumulative abnormal post-earnings announcement return from day +2 to +60;

UE = seasonally differenced earnings surprise scaled by stock price;

UEUp (*UEDown*) = product of the unexpected earnings, *UE*, and the indicator variable, *Up* (*Down*), which takes the value of 1 if *UE* is positive (negative), and 0 otherwise;

Sent = monthly Baker-Wurgler Sentiment Index prevailing at the beginning of the month;

NonlUp and *NonlDown* = square of *UEUp* and the square of *UEDown*, respectively, multiplied by −1; and

MktPE = difference between the aggregate stock market PE of the lagged month and the average market PE of the prior 12 months.

Because the incidence of the positive news dominates the incidence of the negative news, the net effect is to increase the average *UE* during low sentiment periods. Nevertheless, as we report at the bottom of Table 1, the *incidence* of positive and negative earnings surprises is similar across high, medium, and low sentiment periods, with about two-thirds of the total announcements being positive and much of the remaining one-third being negative across the three sub-periods.

III. MAIN RESULTS

Sentiment and Stock Price Sensitivity to Earnings News

We begin our investigation of the role of sentiment in stock price sensitivity to earnings news by reporting the estimates of Equation (2) in Table 2. The intercept, which captures the stock price response to the incidence of earnings that meet or beat the earnings of the firm in the same quarter of the last year, is positive and statistically significant. The coefficient for the variable *Down*, on the other hand, is negative and statistically significant. This coefficient, when added to the intercept, yields a negative value and captures the stock price response to the incidence of earnings that fall short of the earnings four quarters earlier. Both of these results are expected and consistent with the prior literature. The coefficient for the variable *UEUp*, which captures the ERC of positive earnings news when sentiment is zero, is 1.06, and is statistically significant with the t-statistic of 46.36. This is consistent with a large literature in accounting that documents that earnings surprises elicit significant response from stock prices. The coefficient of *UEDown*, which depicts the ERC of the negative earnings news, is 0.266 and is statistically significant with a t-statistic of 11.38. The positive coefficient indicates that the stock price declines more when the absolute value of the negative earnings news is greater, again consistent with the notion that stock price moves in the direction of the earnings surprises. Further, the evidence of a larger coefficient for *UEUp* than for *UEDown* is also consistent with the extant literature, which finds that positive earnings surprises are considered to be more informative than the corresponding negative surprises, possibly due to the tendency of some managers to take an earnings bath (Conrad et al. 2002).

Our primary focus in Table 2 is on the interaction variables that capture the effect of sentiment on ERC for the positive and negative earnings news. The coefficient of the interaction variable, *UEUp* × *Sent*, is a positive 0.037 with a t-statistics of 3.35, which is consistent with our hypothesis, and indicates that the ERC for the announcement of positive earnings news increases with investor sentiment. The reported coefficient estimate for *UEDown* × *Sent* in Table 2 is –0.069 with a t-statistic of –6.26, which is consistent with stock price sensitivity to negative earnings news decreasing with the sentiment. Taken together, the evidence in Table 2 indicates that the response of stock price to both positive and negative earnings news is more positive when sentiment is more bullish.[10]

To assess the economic significance of these coefficients, we first note that the sentiment variable, *Sent*, is a standardized variable with mean 0 and standard deviation of 1. Thus, in Equation (2), the coefficient for *UEUp* (*UEDown*) when *Sent* is 0 (i.e., *Sent* is at its mean) is given by β_0 (γ_0), after accounting for the effect of the other control variables. When *Sent* is equal to 1, that is, it is one

---

[10] We also re-estimate Equation (2) after inserting a stand-alone term, *Sent*, in the model. In untabulated results, we find that the stand-alone *Sent* variable has a coefficient of 0.00067 (t-statistic = 2.38), and the interaction variables, *UEUp* × *Sent* and *UEDown* × *Sent*, have coefficients of 0.023 (t-statistic = 2.29) and –0.053 (t-statistic = –4.61), respectively. We further re-estimate our main model in Equation (2) after replacing the dependent variable of three-day event returns with a longer window return, which captures the abnormal returns beginning two days after the previous earnings announcement to one day after the current announcement. In untabulated results, we find that the results of this sensitivity analysis are similar to those reported in Table 2. The coefficient for *UEUp* × *Sent* is 0.073 with a t-statistic of 1.72, whereas the coefficient for *UEDown* × *Sent* is –0.112 with a t-statistic of 2.56. Thus, the basic patterns in Table 2 seem to hold for the longer return window.

---

*, **, *** Indicate statistical significance at 10 percent, 5 percent, and 1 percent, respectively.
This table provides estimates of the following model:

$$RET_{it} = \alpha_0 + \alpha_1 Down_{it} + \beta_0 UEUp_{it} + \beta_1 UEUp_{it} \times Sent_{t-1} + \gamma_0 UEDown_{it} + \gamma_1 UEDown_{it} \times Sent_{t-1} + \beta_2 NonlUp_{it} + \beta_3 UEUp_{it} \times MktPE_{t-1} + \gamma_2 NonlDown_{it} + \gamma_3 UEDown_{it} \times MktPE_{t-1} + \varepsilon_{it}.$$

The model is estimated using OLS and the pooled data of 392,212 quarterly earnings announcements over the period of 1972–2007. The t-statistics are reported in parentheses and are based on heteroscedasticity consistent standard errors clustered by month.

Variable Definitions:
RET_{it} = cumulative abnormal return calculated per the methodology detailed in Daniel et al. (1997) from day −1 to +1 relative to the earnings announcement date;
UEUp (*UEDown*) = product of the unexpected earnings, *UE*, and the indicator variable, *Up* (*Down*), which takes the value of 1 if *UE* is positive (negative), and 0 otherwise;
Sent = monthly Baker-Wurgler Sentiment Index prevailing at the beginning of the month;
NonlUp and *NonlDown* = square of *UEUp* and the square of *UEDown*, respectively, multiplied by −1; and
MktPE = difference between the aggregate stock market PE of the lagged month and the average market PE of the prior 12 months.

standard deviation above its mean, the coefficient of *UEUp* (*UEDown*) becomes $\beta_0 + \beta_1$ $(\gamma_0 + \gamma_1)$. Similarly, when *Sent* is equal to −1, that is, it is one standard deviation below its mean, the coefficient of *UEUp* (*UEDown*) equals $\beta_0 - \beta_1$ $(\gamma_0 - \gamma_1)$. The estimated coefficients we report in Table 2 indicate that β_0 equals 1.061 whereas β_1 is 0.037, implying that the coefficient of *UEUp* is 1.098 [= 1.061 + 0.037] when *Sent* is high (i.e., one standard deviation above mean) and 1.024 [=

1.061 – 0.037] when *Sent* is low (i.e., one standard deviation below mean). These numbers suggest that the stock price sensitivity to positive earnings news decreases by about 7 percent [= 1.024/1.098 – 1] when we move from periods of high sentiment to periods of low sentiment. On the other hand, the reported estimates of γ_0 and γ_1 are 0.266 and –0.069, respectively, implying that the coefficient of *UEDown* is 0.197 [= 0.266 – 0.069] when *Sent* is high and 0.335 [= 0.266 + 0.069] when *Sent* is low. These numbers suggest that the stock price sensitivity to negative earnings news increases by 70 percent [= 0.335/0.197 – 1] when we move from periods of high sentiment to periods of low sentiment. Thus, the effect of sentiment on the mispricing of negative earnings appears to be more pronounced than that for the positive news.

This asymmetry in the effect of sentiment is consistent with the notion that the incremental cash flow embedded in bad earnings news is more uncertain and difficult to value than the incremental cash flow that is embedded in good earnings news. Thus, investors face greater subjectivity in the valuation of bad news, making the stock price reaction to bad news more susceptible to the prevailing sentiment. To provide some empirical support for this conjecture, we first compute the persistence of good and bad earnings news for each firm using the following autoregressive model for seasonally differenced earnings:

$$\begin{aligned} EPS_{iq} - EPS_{iq-4} = {} & \alpha_0 + \alpha_1(EPS_{qt-1} - EPS_{iq-5}) + \alpha_2 DNeg_{q-1} \\ & + \alpha_3(EPS_{iq-1} - EPS_{iq-5}) \times DNeg_{q-1} + \varepsilon_{iq}. \end{aligned} \tag{4}$$

The variable *DNeg* in the model is a dummy variable that equals 1 if the prior quarter's earnings change is negative, and 0 otherwise. The persistence of good news is captured in the estimated coefficient α_1 in the model, whereas the persistence of bad news is represented by the sum of the two coefficients $\alpha_1 + \alpha_3$. We then compare the cross-sectional *variability* of the estimated firm-level persistence measures of good and bad news. Consistent with our conjecture, we find that standard deviation of the persistence of the bad news (1.258) is greater than the standard deviation of the persistence of good news (0.898). This suggests that the identification and the valuation of the incremental cash flows associated with a bad news signal might be a more subjective task than the corresponding valuation of a good news signal. This could allow sentiment to play a more pronounced role in the pricing of bad than good earnings news.

Turning to the control variables, we include the interaction term between relative market *PE* and earnings surprise following Conrad et al. (2002). They find that the stock price sensitivity to good news is largely unaffected by relative market *PE*, but price sensitivity to bad news increases during periods of high relative market *PE*. Our results, in contrast, show that the coefficient of the interaction between relative market *PE* and positive unexpected earnings is positive with a significant t-statistic of 2.15. Moreover, the coefficient on the interaction between relative market *PE* and negative unexpected earnings (*UEDown*) is negative and insignificant. This indicates that relative market *PE* has no impact on the stock price reaction to bad news. Thus, our results suggest that the significance of relative market *PE* for stock price sensitivity documented by the prior literature largely disappears once we incorporate the effect of sentiment.

In sum, our results are consistent with the view that the behavioral biases of investors, summarized in the form of aggregate investor sentiment, affect how stock prices respond to firm-specific news, and provide support for our hypothesis that the stock price response to earnings news contains both a rational as well as a behavioral component.

Sentiment and Informativeness of Current Earnings for Future Earnings

To examine the alternative explanation that the higher ERC for the good (bad) news during high (low) sentiment periods, which we document in Table 2, simply reflects the greater information content of the news during such periods, we follow the methodology outlined in

Section II. We estimate Equation (3), in which future realized earnings or cash flows are regressed on current earnings surprises, and report the results in Table 3. We are specifically interested in the coefficients for $UEUp \times Sent$ and $UEDown \times Sent$, that is, whether β_1 is positive and γ_1 is negative, as this would suggest that the differential information content of earnings news over time, rather than sentiment, could be driving our results in Table 2.

When the dependent variable is the future realized cash flows, the reported estimates of β_1 and γ_1 in Table 3 are statistically indistinguishable from zero, indicating that the informativeness of earnings news for future cash flows does not vary with sentiment. When the dependent variable is future realized earnings, both the interaction variables become statistically significant but with the "wrong" signs. The estimate of β_1 is negative (–0.198) and significant (t-statistic = –2.13), indicating that the impact of current quarter's positive earnings news on earnings one quarter ahead

TABLE 3

---

*, **, *** Indicate statistical significance at 10 percent, 5 percent, and 1 percent, respectively.

This table provides estimates of the following model:

$$Perf_{iq+1} = \alpha_0 + \alpha_1 E_{iq-3} + \beta_0 UEUp_{iq} + \beta_1 UEUp_{iq} \times Sent + \gamma_0 UEDown_{iq} + \gamma_1 UEDown_{iq} \times Sent + \varepsilon_{iq+1}.$$

The dependent variable, $Perf_{iq+1}$, alternately equals E_{iq+1} or CFO_{iq+1}.

The model is estimated using pooled stock-quarter data. The t-statistics are reported in parentheses and are based on heteroscedasticity consistent standard errors clustered by month.

Variable Definitions:

E_{iq+1} = one-quarter-ahead actual earnings reported in Compustat adjusted according to Livnat and Mendenhall (2006);

CFO_{iq+1} = one-quarter-ahead Cash Flow from Operations reported in Compustat;

E_{iq-3} and CFO_{iq-3} = actual earnings and cash flow from operations, respectively, for three quarters back;

$UEUp$ ($UEDown$) = product of the unexpected earnings, UE, and the indicator variable, Up ($Down$), which takes the value of 1 if UE is positive (negative), and 0 otherwise; and

$Sent$ = monthly Baker-Wurgler Sentiment Index prevailing at the beginning of the month of the announcement of quarter q earnings.

decreases with sentiment. For earnings informativeness to account for our main results, this coefficient should be positive and significant rather than negative and significant. Further, the coefficient on γ_1 is positive (0.605) and significant (t-statistic = 4.41), indicating that the impact of the current quarter's negative earnings news on earnings one quarter ahead *increases* with sentiment. To account for our main results in Table 2, this coefficient should be negative and significant.[11] Overall, the results in Table 3 suggest that the time variation in the information content of earnings cannot explain our results in Table 2 because the information content of earnings is either unrelated to sentiment (when measured using future cash flows), or is related in the "wrong" way (when measured using future earnings).[12]

IV. ADDITIONAL ANALYSES

Do the Pricing Effects of Sentiment Reverse Quickly or Contribute to Drift?

Prior studies on investor sentiment (Baker and Wurgler 2006; Brown and Cliff 2005) suggest that its effects on asset prices persist for some time and reverse only over longer horizons of one to three years. To test whether the impact of sentiment on the pricing of earnings news is temporary or continues into the near future, we examine how sentiment influences the commonly documented post-earnings announcement drift (PEAD) in stock prices. We form deciles of earning surprises and examine how the drift associated with each decile varies across periods of extremely high (top 20 percent) and extremely low (bottom 20 percent) investor sentiment. The drift is based on the abnormal stock returns over the period starting from day +2 relative to the current earnings announcement to a day after the announcement of the next quarter's earnings. Table 4 shows that the post-announcement stock returns for every decile of earnings surprises are lower during the low sentiment periods than during the high sentiment periods. Moreover, while the negative abnormal returns associated with the bottom four deciles of the earnings surprises are significantly negative during the low sentiment periods, the corresponding returns are statistically indistinguishable from zero during the high sentiment periods.

In an alternative simple test of the medium-term continuation of the effect of sentiment, we re-estimate Equation (2) after replacing the dependent variable with the cumulative abnormal returns over the period +2 to +60 relative to the earnings announcement date. We find that the results mirror those documented in Table 2. That is, the coefficient of *UEUp* × *Sent* is positive and significant, and that of *UEDown* × *Sent* is negative and significant. Overall, therefore, it appears that, consistent with the view expressed by Baker and Wurgler (2006) and Brown and Cliff (2005),

---

[11] In additional analysis, we replace the dependent variable with the earnings two, three, and four quarters ahead and find that the results are very similar, in both economic and statistical significance, to those reported in Table 3.

[12] The results in Table 3 differ when we use earnings versus cash flows as the dependent variable. One possibility is that the accruals component of earnings varies systematically over time with sentiment, and the subsequent reversal of this component causes the informativeness of current earnings for future earnings to vary significantly with sentiment. To consider this possibility, we first note that the finance literature links the overpricing of stocks during periods of high sentiment to greater equity issuance and corporate investment, as managers attempt to exploit the mispricing of their firms (Stein 1996; Baker et al. 2003). Corporate investment, in turn, has strong positive association with accruals (Fairfield et al. 2003; Polk and Sapienza 2009). Thus, periods of high sentiment are also likely to be periods of high accruals. The poor future performance commonly associated with high accruals could, therefore, lead to more mean-reversion in the good earnings news that arrives during high sentiment periods than the good news that arrives during low sentiment periods. Similarly, the accruals-related reversals would make the bad earnings news that arrives during high sentiment periods look more persistent than the bad earnings news that arrives during low sentiment periods. This would show up as the negative (positive) association between sentiment and the informativeness of positive (negative) current earnings news for future earnings in Table 3.

*, **, *** Indicate statistical significance at 10 percent, 5 percent, and 1 percent, respectively.

This table documents the drift in stock prices in the period +2 to +60 relative to the earnings announcement date. Returns are abnormal returns calculated following the methodology of Daniel et al. (1997). *UE* is the earnings surprise as defined in Equation (1). We first identify months of extremely high (top 20 percent) and extremely low (bottom 20 percent) sentiment, and then examine the drift associated with the earnings announced during the high and low sentiment months. The sorting of earnings surprise (*UE*) into deciles is relative to the breakpoints identified from the previous calendar quarter.

the impact of sentiment on stock price sensitivity to earnings news is not a temporary phenomenon because it extends to several months following the announcement of earnings.

Contribution of Earnings Mispricing to the Sentiment-Return Relationship

So far, our results show that the stock price reaction during the three days surrounding the announcement of both good and bad earnings news is more positive when sentiment is high than when sentiment is low. Further, the drift in stock prices mirrors the results documented for the three-day event window. The upward (downward) stock price drift following the announcement of good (bad) earnings news is greater during periods of high (low) sentiment than during periods of low (high) sentiment. If sentiment-related mispricing of *earnings* reverses over longer horizons and contributes significantly toward the previously documented negative relation between sentiment and future returns,[13] then we should find that the relation is stronger for stocks that experience large earnings surprise than for stocks that experience no or little earnings surprise.

To investigate this possibility, we first sort firms in each calendar year *y* into quartiles based on the average of the absolute values of all the quarterly earnings surprises during the year.[14] We retain only those firms in this analysis for which the earnings news is available for at least three quarters during the year.[15] We label the firms in quartiles 4 and 1, respectively, as the high-news and low-news firms. We then investigate whether the high-news firms have greater sensitivity to sentiment than the low-news firms by running the following regression, where m and y signify month and year:

---

[13] Prior research has shown that sentiment-related mispricing of stocks reverses in the future (Baker and Wurgler 2006; Brown and Cliff 2005). During high (low) sentiment years, prices are excessively bid up (down), and so the reversal entails a drop (rise) in future stock prices. Future stock returns are, thus, negatively associated with sentiment.

[14] If the news is good and the sentiment is high in year *y*, then the firm becomes overvalued and stock price falls in the subsequent year. Similarly, if the news is bad and the sentiment is high, then the stock price does not fall as much in the current year and thus also becomes overvalued. Hence, regardless of whether it is good or bad news that arrives during high sentiment periods, the firm becomes overvalued. Hence, we use the absolute value of the news rather than the signed value of the news.

$$RET_{HN,m,y} - RET_{LN,m,y} = \alpha_0 + \alpha_1 Sent_{y-1} + \beta_1 RMRF_{m,y} + \beta_2 SMB_{m,y} + \beta_3 HML_{m,y} + \beta_4 UMD_{m,y} + \varepsilon_{m,y}. \tag{5}$$

The dependent variable is the difference between the equal weighted return of the high-news stocks (labeled with subscript *HN*) and the equal weighted return of the low-news stocks (labeled with subscript *LN*). Similar to Baker and Wurgler (2006), we regress the monthly returns in year y on sentiment in year y–1 in this equation. The coefficient of the lagged sentiment, α_1, captures the *differential* sensitivity of the high-news stocks to sentiment relative to that of the low-news stocks. If the association between sentiment and future returns is stronger (i.e., more negative) for the high-news stocks, as we hypothesize, we should find that the coefficient α_1 is negative and statistically significant. The other four variables on the right-hand side of the model represent the three Fama and French (1993) risk factors and the momentum factor, and are meant to control for the differences in the risk exposures of the high-news and low-news stocks. We obtain the monthly observations of these factors from Wharton Research Data Services (WRDS).

The descriptive statistics in Panel A of Table 5 show that the mean (median) value of the average absolute earnings surprise for the low-news firms is 0.002 (0.002). The corresponding mean (median) for the high-news firms is ten times higher at 0.025 (0.020). This gives us some assurance that there is a reasonable variation in the magnitude of the earnings surprises across the low-news and high-news firms. The last two columns show that the mean (median) earnings surprise of those high-news firms for which all the quarters in the year had positive news is 0.028 (0.022). We label these firms as high-positive-news (*HPN*) firms. This sample makes up around 40 percent of the overall high-news sample. For the remaining high-news firms, which have at least one negative earnings surprise during the year, the mean (median) earnings surprise is 0.024 (0.020). We label these as high-negative-news (*HNN*) firms.

Column (2) of Panel B in Table 5 shows that sentiment (*Sent*) is indeed negatively related to the difference in returns between the high- and low-news stocks (coefficient = –0.178, t-statistic = –1.70). This suggests that the mispricing of earnings surprises due to investor sentiment during the short run is reversed in the longer period, and contributes to the relation between sentiment and future returns. The greater the earnings surprise, the greater the sentiment-related mispricing during the short run and, hence, greater the reversal in the long run. The differential effect of sentiment on future returns for the high-news firms is economically significant. Because sentiment is a standardized variable with mean 0 and standard deviation of 1, the coefficient of –0.178 translates into a differential reversal of 0.356 percent (0.178×2) per month for the high-news firms relative to the low-news firms for a change in sentiment from one standard deviation below the mean to one standard deviation above the mean. In terms of statistical significance, we note that the coefficient of sentiment is significant only at the 10 percent level. This is perhaps not surprising given that long-term return analysis presents thorny statistical issues (Lyon et al. 1999) and because the sign and the magnitude of the earnings surprises during the year might be a noisy proxy for the sign and the magnitude, respectively, of all the firm-specific news that arrives during the year.

---

[15] We lose about 40 percent of the sample observations using this filter. Our results, however, are qualitatively similar when we use all firm-years instead of only those with at least three quarters of data.

*, **, *** Indicate statistical significance at 10 percent, 5 percent, and 1 percent, respectively.

This table examines how the short-term mispricing of earnings news contributes to the broader relation between sentiment and future returns. The sample period is from 1973–2007. For each calendar year, we first sort firms based on the average of the absolute value of all the quarterly earnings surprises during the year, after restricting the sample to those firms for which we have the data of at least three quarterly earnings surprises. The firms in the top and bottom quartiles are labeled as high-news (*HN*) and low-news (*LN*) firms, respectively, and are retained for the analysis.

Panel A reports the summary statistics for these two sets of firms. We also divide the high-news sample further into two sub-groups: the firms for which all quarterly surprises were positive are grouped together as high-positive-news firms (*HPN*), whereas the remaining firms with at least one negative earnings surprise are grouped as high-negative-news firms (*HNN*). The summary statistics of these two subsamples of the high-news firms are also reported in Panel A in the last two columns.

In Panel B, we then examine the how the relation between sentiment and future returns varies across various sub-groups of stocks by estimating variations of the following model:

(continued on next page)

TABLE 5 (continued)

$$RET_{HN,m,y} - RET_{LN,m,y} = \alpha_0 + \alpha_1 Sent_{y-1} + \beta_1 RMRF_{m,y} + \beta_2 SMB_{m,y} + \beta_3 HML_{m,y} + \beta_4 UMD_{m,y} + \varepsilon_{m,y}.$$

The subscripts m and y in this equation stand for calendar month and year, respectively. The dependent variable in the first estimation, reported in Column 2 of Panel B, is the difference in the returns of the equal weighted portfolios of the high-news (*HN*) stocks and the low-news (*LN*) stocks. *Sent* is the annual Baker-Wurgler Sentiment Index. In this model, we regress the monthly returns in year y on the sentiment for calendar year y–1. The coefficient of the lagged sentiment α_1 in the equation captures the *differential* sensitivity of the high-news stocks to sentiment relative to that of the low-news stocks. *RMRF*, *SMB*, *HML*, and *UMD* signify the market, size, value, and momentum factors, respectively. In the last three columns of Panel B, we report the estimates of this model after substituting the dependent variable with the difference between the returns of the high-positive-news and low-news firms (Column 3), the difference between the returns of the high-negative-news and low-news firms (Column 4), and the difference between the returns of the high-negative-news and high-positive-news firms (Column 5). The t-statistics are reported in parentheses and are based on heteroscedasticity consistent standard errors.

Our previous analysis in Table 2 shows that the impact of sentiment on the price sensitivity to earnings surprises (or earnings-mispricing due to sentiment) is higher for bad news than for good news. Therefore, it is likely that the subsequent reversals and the corresponding negative relation between sentiment and future returns is also stronger for stocks that experience negative earnings news than for the stocks that experience positive earnings news. To investigate this possibility, we split the high-news firms into positive high-news and negative high-news firms. The firms whose quarterly earnings surprises during year y–1 are all of positive sign are grouped together as the high-positive-news (*HPN*) firms. The rest of the firms, whose quarterly earnings surprises include at least one negative surprise, form the other group labeled as the high-negative-news (*HNN*) firms. This criterion yields us a somewhat balanced split of the high-news sample and reflects the relative scarcity of the negative earnings surprises.[16]

We then examine the differential relation between sentiment and future returns for the high-negative-news stocks relative to the high-positive-news stocks by modifying the dependent variable in Equation (5) and report the results in the last three columns of Panel B in Table 5. Column (3) reports the estimates when the dependent variable is the difference in the returns of the high-positive-news firms (*HPN*) and low-news firms. Here the coefficient of *Sent* becomes insignificant (coefficient = –0.067, t-statistic = –0.61). On the other hand, in Column (4), we report the estimates of the model when the dependent variable is the difference in the returns of the high-negative-news firms (*HNN*) and the low-news firms. Here the coefficient of *Sent* becomes more pronounced and statistically significant (coefficient = –0.245, t-statistic = –2.08). This suggests that bad earnings news is the primary source of the greater sentiment-future return relation for the high-news stocks compared to the low-news stocks reported in Column 2. Finally, in Column (5), we more directly examine the differential sentiment-driven mispricing of the bad and good earnings news. Here the dependent variable is the difference between the returns of the high-positive-news firms (*HPN*) and high-negative-news firms (*HNN*). The coefficient on sentiment is now negative and significant (coefficient = –0.181, t-statistic = –1.81). This shows that the reversal for the bad news sample is significantly higher than the reversal for the all good news sample. Overall, the results in Table 5 suggest that sentiment-related mispricing of earnings news contributes significantly to the negative relation between sentiment and future returns, and this is especially true for negative earnings news.[17]

---

[16] Including only those firms whose quarterly earnings surprises are *all* negative leaves us with very few observations (13 percent of the high-news sample).

Cross-Sectional Variation in the Role of Sentiment

Extant literature argues that broad waves of sentiment will have greater effects on stocks that are harder to value and more difficult to arbitrage (Lemmon and Portniaguina 2006; Qiu and Welch 2006; Baker and Wurgler 2006). Specifically, Baker and Wurgler (2006) suggest that small, young, high volatility, non-dividend-paying, distressed (i.e., low market-to-book), and extreme growth (i.e., high market-to-book) stocks are more likely to be affected by sentiment,[18] while large, mature, stable, high-dividend-paying, and medium-growth companies are likely to be affected less or even negatively. Investors might see these latter firms as safe heavens during times of low sentiment (Baker and Wurgler 2007).

We hypothesize that the effect of sentiment on the ERC would also be more pronounced for small, young, high volatility, non-dividend-paying, distressed (i.e., low market-to-book), and extreme growth (i.e., high market-to-book) stocks. We argue that sentiment influences the ERC because investors value the incremental cash flows embedded in earnings announcements optimistically (pessimistically) during periods of high (low) sentiment. The arguments of Baker and Wurgler (2006) imply that the effect of sentiment on the (mis)valuation of the incremental cash flows is likely to be greater if the cash flows are more uncertain and difficult to assess, which is likely to be the case for earnings of speculative stocks in general.

To test this hypothesis, we classify stocks at the end of each month into groups that are more or less exposed to sentiment based on five individual firm characteristics following the methodology in Baker and Wurgler (2006). The first three characteristics—size, age, and stock return volatility—are computed every month for each stock using the CRSP monthly tape. *Size* is the market capitalization of the stock. *Age* is the number of years since the firm first appeared on CRSP, measured to the nearest month. *Stock return volatility* is the standard deviation of monthly returns over the preceding 12 months. The last two characteristics—dividend payout and market-to-book ratio—are computed once a year at the end of June, and are then assigned to each of 12 subsequent months. *Dividend payout* is the annual dividend divided by the annual earnings in the most recent fiscal year, and is obtained from Compustat. Market-to-book ratio (*MEBE*) is computed by using the book value from Compustat for the most recent fiscal year that ended during calendar year $y-1$. This book value is then matched with the market value of the stock as of the end of June in year y to compute *MEBE* ratio as of June in year y.

We then use each individual firm characteristic to identify one portfolio that is likely to be affected more by sentiment, and a second portfolio that is likely to be affected less, or even negatively, by sentiment. We classify firms that fall in the bottom quintile based on size and age of the overall CRSP sample using NYSE breakpoints as small and young firms, respectively. We classify their counterparts in the top quintile as large and mature firms, respectively. These are the firms that are relatively easier to value and arbitrage. Similarly, for stock return volatility, firms that fall in the top (bottom) quintile are classified as volatile (stable) firms, and are expected to be affected more (less) by sentiment. For classification on dividend payout, all the firms that do not pay dividends are grouped together as non-payers. These are the firms that are more exposed to sentiment. The firms that fall into the top quintile of the remaining dividend-paying firms in the CRSP-Compustat merged dataset using NYSE breakpoints are then classified as high payers. These are the firms that are expected to be less exposed to investor sentiment.

---

[17] In additional analysis, we re-estimate Equation (5) for the subsamples of small, young, volatile, and extreme book-to-market stocks (below their median break points). Since the number of stocks each month in the high- and low-news portfolios drops further, we exclude the top and bottom 1 percent of the months identified as influential using the Belsley et al. (1980) methodology. We find that our results in Table 5 continue to hold. For instance, when we estimate the model for small stocks, the coefficients of *Sent* for the four columns in Panel B are, respectively, –0.178 (t-statistic = –1.97), –0.043 (t-statistic = –0.45), –0.259 (t-statistic = –2.49), and –0.177 (t-statistic = –2.30). Estimates for the model for the non-dividend-paying stocks are not reliable because of the prohibitively small number of stocks (e.g., less than 20 in several months) in the portfolios that make up the dependent variables.

[18] They also suggest that loss firms are difficult to value, but since our study focuses only on profitable firms, we do not analyze loss firms.

Baker and Wurgler (2006) predict and find evidence that the effect of sentiment on book-to-market sorted portfolios is roughly U-shaped. Stocks that are more exposed to sentiment reside in the extreme high and low deciles, whereas staid stocks that are less exposed to sentiment are typically found in the middle. Accordingly, we combine the two extreme deciles sorted on market-to-book ratio into one portfolio, which we then expect to be influenced more by sentiment. The stocks in the middle quintile are classified as medium *MEBE* stocks—these are expected to be less affected by sentiment.

To investigate the cross-sectional differences in the impact of sentiment, we estimate Equation (2) separately for the subsamples of stocks classified on the five individual stock characteristics. In doing so, the classification of firms into portfolios at the end of each month is matched to the earnings announcements of the subsequent month. Our expectation is that the interaction variables involving sentiment, which capture the effect of sentiment on the ERC, are more pronounced for the portfolios of firms that Baker and Wurgler (2006) argue are more exposed to sentiment than the firms in their corresponding opposite portfolios.

In addition to studying the above set of firm characteristics separately, we also construct a composite measure based on the five individual characteristics, and study how stocks in the extreme quintiles sorted on this composite measure are affected by sentiment. To do so, we extract the first principle component of the decile ranks of the five individual characteristics.[19] We then sort the stocks each month based on this composite factor. The stocks that fall in the bottom 20 percent are categorized as *More Exposed*, whereas those stocks that are among the top 20 percent are classified as *Less Exposed*. The effect of sentiment on the ERC should be more (less) pronounced for the former (latter) group of stocks.

The results of our cross-sectional analyses are reported in Table 6. Each panel of Table 6 reports the estimates of Equation (2) for two sub-groups of stocks sorted on one of the firm characteristics. In Panel A, we sort stocks on the composite measure, whereas in each of Panels B through F, we classify stocks based on size, age, return volatility, dividend payout, and *MEBE* ratio, respectively. In each panel, the first group of stocks is the one that is expected to be influenced more by sentiment and the latter group is the one expected to be influenced less.

Focusing first on our composite measure in Panel A, it is evident the effect of sentiment is more pronounced for the stocks that we classify as *Exposed* than for the stocks labeled as *Not Exposed*. The coefficient on the interaction variable, $UEUp \times Sent$, is positive and significant, as predicted by our hypothesis, for the *Exposed* stocks (coefficient = 0.038, t-statistic = 2.67). However, for the *Not Exposed* stocks, the estimated coefficient is negative and significant (coefficient = −0.051, t-statistic = −2.54), indicating that for these firms, sentiment operates in the opposite direction compared to the *Exposed* stocks. This result is consistent with the idea posited by Baker and Wurgler (2007) that

---

[19] We first adjust the ranks of all characteristics such that low ranks on each characteristic are associated with the stocks that are more affected by sentiment. Specifically, we reverse the ranks for stock return volatility, such that more volatile stocks have lower ranks. Similarly, for *MEBE* we combine the two extreme deciles and assign them the rank of 1.5, combine deciles 2 and 9 and assign them the rank of 3.5, and so on. The middle two deciles then get the rank of 9.5. Finally, the rank for dividend payout equals 0 for the non-payers; the remaining dividend-paying stocks are ranked from 1 through 10.

(continued on next page)

TABLE 6 (continued)

---

*, **, *** Indicate statistical significance at 10 percent, 5 percent, and 1 percent, respectively.
We estimate the following regression for various sub-groups of stocks, and report the results in this table:

$$RET_{it} = \alpha_0 + \alpha_1 Down_{it} + \beta_0 UEUp_{it} + \beta_1 UEUp_{it} \times Sent_{t-1} + \gamma_0 UEDown_{it} + \gamma_1 UEDown_{it} \times Sent_{t-1} \\ + \beta_2 NonlUp_{it} + \beta_3 UEUp_{it} \times MktPE_{t-1} + \gamma_2 NonlDown_{it} + \gamma_3 UEDown_{it} \times MktPE_{t-1} + \varepsilon_{it}.$$

The model is estimated using OLS and the pooled data of quarterly earnings announcements over the period of 1972–2007. Cross-sectional characteristics we use to identify hard to value stocks are *size*, *age*, *volatility*, *market-to-book ratio*, and *dividend payment*. The bottom (top) 20 percent of the first principle component of these characteristics is defined as hard-to- (easy-to-) value stocks. Hard-to-value stocks are labeled *Exposed* Stocks and easy-to-value stocks are termed *Not Exposed* Stocks.
Panel A shows the estimates of the above regression for *Exposed* and *Not Exposed* Stocks.
Panels B through F report the estimates for small (large), young (mature), volatile (stable), non-dividend-paying (high-dividend-paying) stocks, and growth/value (others).
The t-statistics are reported in parentheses and are based on heteroscedasticity consistent standard errors and clustered by month.

Variable Definitions:
RET_{it} = cumulative abnormal return calculated per the methodology detailed in Daniel et al. (1997) from day −1 to +1 relative to the earnings announcement date;
UEUp (*UEDown*) = product of the unexpected earnings, *UE*, and the indicator variable, *Up* (*Down*), which takes the value of 1 if *UE* is positive (negative), and 0 otherwise;
Sent = monthly Baker-Wurgler Sentiment Index prevailing at the beginning of the month;
NonlUp and *NonlDown* = square of *UEUp* and the square of *UEDown*, respectively, multiplied by −1; and
MktPE = difference between the aggregate stock market PE of the lagged month and the average market PE of the prior 12 months.

the effect of sentiment might even reverse for some of the stocks that are categorized by sentiment-driven investors as bond-like investments. Specifically, Baker and Wurgler (2007) argue that firms that are large, mature, stable, and pay stable streams of high dividends might be perceived by investors as bond-like investments, and might experience overpricing (underpricing) in periods of low (high) sentiment as investors look for safe havens (high growth) for their investments. The estimated coefficients for *UEDown* × *Sent* are negative for both groups of stocks, indicating that effect of sentiment on the ERC of bad news is pervasive across the whole cross-section of stocks. Even so, the magnitude and the statistical significance of the coefficient is somewhat greater for *Exposed* stocks (coefficient = −0.080, t-statistic = −4.27) than for *Not Exposed* stocks (coefficient = −0.047, t-statistic = −2.20). Overall, the results in Panel A are broadly in line with our prediction that the effect of sentiment on stock price sensitivity to earnings news is more pronounced for harder to value and difficult to arbitrage stocks.

The results in Panels B to F are generally similar to those documented in Panel A above. The ERC for good news increases with sentiment for the small, young, volatile, non-dividend-paying, and the extreme *MEBE* firms, and the effect is statistically significant. In contrast, for large, mature, stable, high-dividend-paying, and moderate growth firms, the ERC for good news either decreases with sentiment or is insignificantly related to sentiment. The ERC for bad news decreases with sentiment for all the firms, but the statistical significance of the relation is greater for small, young, volatile, non-dividend-paying, and extreme market-to-book firms than for the corresponding large, mature, stable, high-dividend-paying, and medium market-to-book ratio firms. The results in Table 6 provide general support for the notion that the effect of sentiment on the stock price sensitivity to news varies cross-sectionally, and is stronger for firms that the prior sentiment literature finds are more affected by sentiment.

V. ROBUSTNESS CHECKS

Monthly Regressions

The stock returns associated with the earnings announcement that are close to each other in time are likely to be cross-sectionally correlated. In the regressions so far, the sample used is a pooled cross-sectional time-series dataset, and the test statistics are corrected for this cross-correlation by computing standard errors that are clustered by month. To check the robustness of our results, in this section, we adopt an alternative empirical strategy to control for the cross-correlations in the data. We first compute the average earnings response coefficients for each calendar month, and then regress the average monthly earnings response coefficients on investor sentiment at the beginning of the month to test whether sentiment influences the ERCs. Specifically, we estimate the following regression each month to compute the average ERC for each month for good as well as for bad news:

$$RET_{it} = \alpha_0 + \alpha_1 Down_{it} + \beta_1 UEUp_{it} + \gamma_1 UEDown_{it} + \delta_1 NonlUp_{it} + \delta_2 NonlDown_{it} + \varepsilon_{it}. \tag{6}$$

The coefficients β_1 and γ_1 are estimates of the ERCs for good news and bad news, respectively, for each calendar month t. We drop months that have fewer than 200 earnings announcements to ensure that the monthly estimates are not noisy.[20] We then use the estimated ERCs as the dependent variables in the second stage regressions of the following form:

$$ERC_t = \alpha_0 + \alpha_1 Sent_{t-1} + \alpha_2 MktPE_{t-1} + \varepsilon_t, \tag{7}$$

where *ERC* is either the ERC for good news or the ERC for bad news, *Sent* is the sentiment at the beginning of the month, and *MktPE* is the relative market *PE* computed at the beginning of the month. In the regression involving the ERC of good news, we expect the coefficient on *Sent* to be positive. Correspondingly, in the regression involving the ERC for bad news, we expect the coefficient on *Sent* to be negative.

The results are shown in Table 7. Consistent with the results documented in Table 2, the monthly ERC for good news is increasing in sentiment (coefficient = 0.056, t-statistic = 1.75), and the ERC for bad news is decreasing in sentiment (coefficient = −0.077, t-statistic = −2.08). These results support our main hypothesis that the prevailing investor sentiment sways the stock price response to earnings surprises in the direction of the sentiment.

Earnings Surprises Defined Relative to Analyst Forecasts

We argued earlier in the paper that the seasonally differenced earnings surprises are a better measure of earnings news to examine how sentiment influences the stock price sensitivity to earnings news. Nevertheless, in this section we examine how stock price sensitivity to news varies with sentiment when the news is defined by comparing the actual earning with the consensus analyst forecast. This alternative earnings news, which we label as forecast error (*FE*), is defined as follows:

$$FE = \frac{\text{Actual Earnings} - \text{Consensus Earnings Forecast}}{\text{Beginning of the Month Stock Price}}. \tag{8}$$

---

[20] This removes 11 months from a total of 432 months in our sample period. In an alternative treatment of the noisy estimates for individual months, we drop the months that are identified as "influential" using the Belsley et al. (1980) methodology. Our results remain robust.

TABLE 7

Investor Sentiment and ERC Computed Monthly

Explanatory Variables	Dependent Variable	
	ERC_{Up}	ERC_{Down}
Intercept	1.228***	0.426***
	(40.95)	(9.68)
Sent	0.056*	−0.077**
	(1.75)	(−2.08)
MktPE	0.003	−0.003
	(0.34)	(−0.27)
Number of observations	421	421
Adjusted R^2	1.00%	1.00%

*, **, *** Indicate statistical significance at 10 percent, 5 percent, and 1 percent, respectively.
This table provides estimates of the following model:

$$ERC_t = \alpha_0 + \alpha_1 Sent_{t-1} + \alpha_2 MktPE_{t-1} + \varepsilon_t.$$

The model is estimated using OLS and on a sample of 421 months over the period of 1972–2007.
The t-statistics are reported in parentheses and are based on heteroscedasticity consistent robust standard errors.

Variable Definitions:
ERC = earnings response coefficient for month *t* calculated from Equation (6);
ERCUp (*ERCDown*) = ERC for positive (negative) unexpected earnings;
Sent = monthly Baker-Wurgler Sentiment Index prevailing at the beginning of the month; and
MktPE = difference between the aggregate stock market PE of the lagged month and the average market PE of the prior 12 months.

Consensus earnings forecast in Equation (8) is the last median forecast available in the I/B/E/S summary file prior to the earnings announcement date. Actual earnings are also extracted from the I/B/E/S summary file. The stock price in the denominator is the share price as at the beginning of the month in which earnings is announced. The actual and forecasted earnings as well as the share price are adjusted for stock splits. For our initial sample of earnings announcements in Table 1, we extract the relevant data from the I/B/E/S summary file for the period 1985 through 2007. Our final sample of analyst forecast errors includes 196,243 observations.

We then replace *UE* with *FE* in Equation (2) to examine how investor sentiment influences the stock price sensitivity to earnings news when the news is defined based on analyst forecast errors. In untabulated results, we find that the coefficient on good news interacted with sentiment is positive and significant (coefficient = 0.227, t-statistic = 2.12), while the coefficient on bad news interacted with sentiment is negative and significant (coefficient = −0.157, t-statistic = −2.93). These results show that the evidence of the influence of sentiment on stock price sensitivity to earnings news continues to hold when we define earnings news by comparing actual earnings to analyst forecasts.

Controlling for Additional Cross-Sectional Determinants of ERC

Prior literature indicates that the ERC could also vary systematically with certain other firm-specific variables, such as size, growth, past earnings volatility, and earnings persistence (DeFond and Park 2001). To examine the robustness of our results to these cross-sectional effects, we interact *UEUp* and *UEDown* with each of *Size*, *MB*, *EVOL*, and *PERS*, and add these as additional controls to our regression in Table 2. *Size* is the decile rank based on the market capitalization of the stock in month *t*–1. *MB* is the decile rank based on the market-to-book ratio. *EVOL* is the standard deviation of previous four quarters' actual earnings divided by the beginning of the month stock price. Finally, *PERS* is the persistence of earnings measured as the coefficient from an autoregressive model, which is seasonally differenced.

In untabulated results, we find that the magnitude of the coefficients and the statistical significance for our key variables, *UEUp* × *Sent* and *UEDown* × *Sent*, remain largely similar to what we report in Table 2 for the parsimonious model. The coefficient on *UEUp* × *Sent* is 0.027 with a t-statistic of 2.28, and the coefficient on *UEDown* × *Sent* is –0.053 with a t-statistic of –4.34. The coefficients associated with the control variables mostly show up with the expected signs.

Loss Firms

We remove the loss firms from our main analysis because the low earnings response coefficients for such firms (Hayn 1995) might make them unsuitable to study the effect of sentiment on ERC. Nevertheless, in this section, we estimate Equation (2) for the subsample of loss firms. In untabulated results, we find that the impact of sentiment on ERC is in the same direction as that of the profitable firms but is not statistically significant. The coefficient on *UEUp* × *Sent* is 0.013 with a t-statistic of 0.79, whereas the coefficient on *UEDown* × *Sent* is –0.011 with a t-statistic of –1.37. The explanatory power of the model for loss firms, however, is far smaller than that for profitable firms, mirroring the findings of Hayn (1995).

VI. CONCLUSION

Most prior studies on stock price response to earnings follow the efficient market paradigm, and examine cross-sectional differences in the stock price response to earnings. This study takes a time-series approach and helps answer the call for more work that incorporates the findings of behavioral finance in capital market research in accounting (Lee 2001). Using a recent proxy of investor sentiment constructed by Baker and Wurgler (2006, 2007), we examine how the stock price reaction to earnings news varies with investor sentiment. Our results show that the stock price response to good earnings news is higher during periods of high sentiment, whereas stock price reaction to bad earnings news is higher during periods of low sentiment. This is consistent with the notion that as sentiment increases, investors place increasingly optimistic valuations on the incremental cash flows embedded in earnings announcements. The relation between sentiment and stock price response is more pronounced for stocks that have more subjective valuations, that is, small stocks, young stocks, non-dividend-paying stocks, volatile stocks, and growth and distressed stocks.

Our evidence that stock price reactions to earnings news contain both rational and irrational components has implications for the event study literature. Many of these studies attempt to quantify the valuation implications of accounting information. Our results imply that value and price could diverge in the short run because of the impact of behavioral biases on how accounting information is impounded into prices. Hence, relying solely on the short-term market reaction as a measure of the valuation impact of accounting information may be insufficient. Researchers need to look beyond the immediate stock price response and consider additional information signals, such as the longer term accounting and stock price performance, to fully understand the implications of an information event on the fundamental value of the firm.

We also connect the sentiment-related (mis)pricing of earnings to the broader effect sentiment has on prices and future returns. Despite several papers that establish a relation between sentiment and mispricing of stocks (Baker and Wurgler 2006; Lemmon and Portniaguina 2006; Qiu and Welch 2006), the precise channel(s) by which sentiment causes such mispricing is not well understood. Our evidence adds to the sentiment literature by identifying misreaction to earnings news as one possible channel through which sentiment causes mispricing of stocks.

Do Unverifiable Disclosures Matter? Evidence from Peer-to-Peer Lending

Jeremy Michels
University of Colorado Boulder

ABSTRACT: The role of disclosure in attenuating market inefficiencies has been the subject of extensive research. While costless, voluntary, and unverifiable disclosures are unlikely to be credible sources of information, prior research demonstrates that individuals' decisions can be influenced by uninformative content. I use a unique dataset from a peer-to-peer lending website, Prosper.com, to demonstrate an economically large effect of voluntary, unverifiable disclosures in reducing the cost of debt. My results show an additional unverifiable disclosure is associated with a 1.27 percentage point reduction in interest rate and an 8 percent increase in bidding activity.

Keywords: *voluntary disclosure; cost of debt; asymmetric information; microfinance; behavioral economics; Prosper.com.*

Data Availability: *All data are publicly available from sources identified in the paper.*

I. INTRODUCTION

The role of disclosure in attenuating inefficiencies in financial markets has been the subject of extensive research.[1] Generally, these studies focus on mandated and audited financial reports. The lack of good measures for voluntary disclosures limits empirical work in this area. In the absence of any cost, it is unclear that voluntary disclosures could be seen as a credible source of information and thus should not influence investment decisions. However, prior research in psychology and behavioral economics demonstrates that people incorporate objectively uninformative content into their decisions in certain circumstances (Nisbett et al. 1981; Gilbert

I thank John Harry Evans III and Steven Kachelmeier (the editors), Alan Jagolinzer, Bjorn Jorgensen, John Lynch, Paul Madsen (discussant), Steve Rock, and Lisa Sedor (discussant) for many insightful remarks as well as seminar participants at the University of Colorado at Boulder, 2010 Western Regional American Accounting Association Meeting, 2011 American Accounting Association Annual Meeting, and two anonymous reviewers for their helpful comments. I also gratefully acknowledge financial support from the AAA/Grant Thornton Doctoral Dissertation Award for Innovation in Accounting Education.

DESCRIPTION

I would like to thank the potential lender for reading this first and foremost. The amount I am asking for is for a business start up cost and would be paid back as soon as 3 months considering I will have many customers in that amount of time. Im offering a very valid solution for those that are seeking a true income opportunity. I do attend a church and am very active in it. I also work full time at a company Ive been employed at for over a year. Please help me if you could, thank you and Id be open to any ?'s you may have.
Marc [LAST NAME DELETED]

et al. 1993; DellaVigna and Gentzkow 2009). Therefore, the influence of voluntary, unverifiable disclosures on investing decisions is an interesting empirical question.

In this study, I use a unique dataset of unsecured personal loans, made to individuals, originated through Prosper.com[2] to investigate the relationship between voluntary, unverifiable disclosures and the cost of debt. Prosper.com is an online, peer-to-peer lending marketplace that provides a service for lending that is similar to eBay.com's service for consumer products. On the Prosper website, potential borrowers apply for a loan by creating a loan listing. The loan listing states the amount of money they wish to borrow and the maximum interest rate they are willing to pay. Figures 1 and 2 give examples of loan listings. Potential lenders[3] bid on portions of loans by setting the minimum interest rate that they are willing to receive and the amount of the loan they wish to fund.

---

[2] All data used in this study are publicly available at http://www.prosper.com/tools/

[3] Lenders, as they are referred to here, are actually purchasing loans, making them technically loan buyers. However, for simplicity I refer to them as lenders throughout the paper.

DESCRIPTION

Purpose of loan:
This is a very safe investment for anyone bidding on this listing. I will use this loan to payoff two very high interest credit cards that I have with Household Bank. They went over the limit and I was charge extra fees(reason for $289 deliquent). I want to pay them off to begin reducing my debt burden and increse my credit score for the future.

My financial situation:
I am currently a doctoral student with a full-time job, a part-time job, two kids and a husband. My husband and I are homeowners with very recent credit issues due his hospitilization at the beginning of the this year. This caused us to use all available and excess funds to maintain. My dti doesn't reflect my part-time income because it is to new to verify. I can assure you that I would have no problem paying this loan and more than likely it will be paid off sooner than the total time allowed. I really want to get rid of these Household cards and begin to rebuild my credit back to its original state. I barely missed the "D" credit grade by two points.

Monthly net income: $ 2100 ($1200 part-time)

Monthly expenses: $ 1733
Housing: $ 0 (husband pays this)
Insurance: $ 130 (my half of auto and life)
Car expenses: $ 401
Utilities: $ 140 (my half)
Phone, cable, internet: $ 127
Food, entertainment: $ 150 (my half)
Clothing, household expenses $ 100 (my half)
Credit cards and other loans: $ 525
Other expenses: $ 260 (my half of daycare)

As you can see, once the part-time income kicks in there will be plenty left to pay this loan. Also, when I pay the two Household cards, it will free up about $200 which can go towards the prosper loan.

While Prosper verifies borrowers' identities and provides certain information obtained from their credit reports, a borrower's loan listing may also include voluntary and unverified personal information, such as intended use of proceeds, interest rates on other debts, explanations for poor credit ratings, or a picture. Using the natural variation in the amount of these voluntary, unverified disclosures in the loan listings, I identify the effect these disclosures have on the number of bids a loan listing receives and the final interest rate on a loan. Data are available for both successful loan listings that resulted in a loan and unsuccessful ones that did not receive enough bids to fund the listing.

My results show that these voluntary disclosures made in loan listings do affect the loans' interest rates. More unverifiable disclosures are associated with a lower interest rate on a loan. Additionally, more unverifiable disclosures increase the bidding activity on a loan listing. These effects are economically large: an additional disclosure is associated with a 1.27 percentage point reduction in interest rate and an 8 percent increase in bidding activity. Given that these essentially costless disclosures reduce interest costs for borrowers, it may seem surprising that not all borrowers make as many voluntary disclosures as possible, regardless of their truthfulness. At least two explanations may account for this behavior. First, the borrowers on Prosper may not fully understand the effectiveness of disclosures in reducing their interest costs. If the market had persisted,[4] then it is possible that learning would have occurred and the amount of disclosures made would have increased. Second, borrowers may be reluctant to use misleading disclosures to reduce their interest rates. This second argument is consistent with work demonstrating an aversion to lying, even when truth-telling is costly (Evans et al. 2001; Gneezy 2005).

My results contribute to a literature that demonstrates the role of presentation and persuasion in decision making by showing that unverifiable disclosures influence investors' decisions in a natural setting with large economic consequences. These findings may interest regulators as these nontraditional financial markets grow in prevalence. Since Prosper's inception in 2006, several other peer-to-peer lending sites have been established, such as Lending Club and Loanio. These online markets have already garnered the attention of the U.S. Securities and Exchange Commission, which imposed a cease-and-desist order against Prosper in 2008, determining that the website must register under the Securities Act of 1933.[5]

This study's findings also have implications for banking and microfinance. Prior research demonstrates the importance of relationships between borrowers and lenders when information asymmetries are severe (Petersen and Rajan 1994; Berger and Udell 1995). In the absence of a relationship, many microfinance institutions rely on group lending and liability to overcome adverse selection issues. While groups of affiliated lenders exist on Prosper, these groups do not have joint liability for the loans of their members. In the absence of group liability, methods developed by microfinance institutions to manage incentives include offering very small, but successively larger loans, and threatening to cut off access to future credit in the case of default (Armendariz de Aghion and Morduch 2010). However, in the context of Prosper, competition among lenders, and other lending websites, is likely to undermine the success of such efforts. Also, repeated borrowing is observed to only a limited degree. Thus, the Prosper marketplace offers an opportunity to study adverse selection problems in lending when traditional remedies are not available. Results indicate participants in the Prosper marketplace appear to be willing to rely on unverifiable disclosures to overcome informational asymmetries.

Finally, this study's setting offers several advantages over studies of voluntary disclosures by publicly traded firms. First, the direction of causality is clearer in the current study than in those using publicly traded firms. In this paper's setting, the disclosures must precede any investment decision. In studies using publicly traded firms, the timing of events (that is, the disclosure and change in firm performance or value) is often less clear. Further, disclosure measures in studies of publicly traded firms are often incomplete, as firms can make disclosures through many alternative avenues, such as annual reports, management forecasts, or conference calls. In this study, all information available to potential lenders is contained in the loan listing, reducing the potential for incomplete measures. Last, most disclosures made by public firms, such as management forecasts, are verifiable in at least an *ex post* sense, giving them some level of credibility. Truly unverifiable disclosures by public firms compose such a small portion of the total information surrounding the firm that it is difficult to identify the effect of these disclosures. A natural solution to this problem is to examine disclosure effects in less developed markets (Verrecchia 2001). My paper contributes to the accounting literature by using such a setting to understand the impact of unverifiable disclosures on participants in a real world market. As Verrecchia (2001, 174) notes, "[A]s the theory of disclosure matures, it seems reasonable to inquire whether the empirical literature can provide additional insights into the economic consequences of disclosure."

---

[4] Loans on Prosper are no longer priced through the bidding process analyzed in this study.

[5] Prosper has since registered and is again operational. All data in this study precede this action.

The remainder of the paper is organized as follows. Section II outlines prior research related to disclosure and develops hypotheses. Section III describes the data source. Section IV discusses the research design. Section V details the main results, while Section VI presents alternative models to test for robustness. Section VII examines the association of unverifiable disclosures and loan performance. Section VIII concludes.

II. RELATED RESEARCH AND HYPOTHESIS DEVELOPMENT

Several contemporaneous working papers also examine the setting of the Prosper marketplace. Some of these studies examine the social aspects of Prosper, such as whether membership in a group of affiliated borrowers affects the success of loan listings (Freedman and Jin 2008; Lin et al. 2009).[6] Other studies examine aspects of the pictures of borrowers included in loan listings to investigate the effect of demographic characteristics such as gender, age, or race (Herzenstein et al. 2008; Pope and Sydnor 2011). Duarte et al. (2010) examine even more subjective aspects of borrower pictures, including trustworthiness and attractiveness. Herzenstein et al. (2011) examine claims of similarly subjective characteristics, such as trustworthiness or piety, in listings. Klafft (2008) offers an overview of how credit information and borrower-provided pictures are related to listing success, while Iyer et al. (2010) investigate how closely lenders can infer actual credit scores. Several of these studies attempt to control for information in the narrative description of the loan listings. Proxies used include word count (Freedman and Jin 2008; Lin et al. 2009), indicator variables for "general" or "specific" personal information (Herzenstein et al. 2008), or the residual of a regression of interest rate on credit variables (Iyer et al. 2010). Note this last measure is only available for successful listings that result in loans.

The present study differs from these works in that I code for the presence of specific disclosures in the loan listings. The unverifiable disclosure measure that I develop allows me to investigate specifically which elements of the loan listing description lenders respond to. I discuss this disclosure measure in detail in Section IV. I am aware of no other study that codes for the presence of particular disclosures in the loan listings.

Empirical studies of disclosure typically focus on firms listed on major exchanges, where voluntary disclosures represent a small fraction of the available information relative to mandatory, regulated filings. This research generally finds that costs of capital are decreasing in the amount of disclosure (Botosan 1997; Sengupta 1998). Sivakumar and Waymire (1994) offer some insight into the effects of disclosures in an unregulated environment by investigating stock market reactions to voluntary disclosures for companies listed on the New York Stock Exchange during 1905–1910. Reporting requirements were minimal during this time. Annual earnings disclosures were mandatory; however, there were no accounting standards or audit requirements. Nonetheless, significant changes in price and trading volume are observed in association with discretionary disclosures during this period, suggesting that the disclosures were seen as at least partially credible. In a similar vein, Price (2000) investigates the association between earnings-related disclosures by franchisers and the fees they charge to franchisees. Disclosure of earnings by franchisers is optional. If disclosed, then the earnings claim is not subject to verification. The study indicates that franchisers who disclose earnings charge their franchisees higher fees. The willingness of franchisees to accept these fees suggests that they perceive these earnings disclosures to be credible. In the context of initial public offerings (IPOs), Leone et al. (2007) demonstrate that firms that volunteer more detailed intended-use-of-proceeds disclosures enjoy less IPO underpricing. Lang and Lundholm (2000) find firms increase voluntary disclosures before seasoned equity offerings to "hype" their stock. Upon the announcement of the offering, the market penalizes these firms, as it suspects their ulterior motive for the increase in disclosure. However, the reduction in stock price is incomplete, suggesting firms can use "hype" to reduce their cost of equity capital.

---

[6] Groups on Prosper do not have joint liability for the loans of their members, unlike some other micro-lending settings.

In summary, empirical research on unverifiable disclosures generally indicates market participants perceive such disclosures as being at least partially credible. However, voluntary disclosures made by firms, such as management forecasts, are often verifiable in an *ex post* sense. It is not clear that these results would generalize to a setting in which there is no opportunity for *ex post* settling up. While shareholders may have the opportunity to sue for misleading information, lenders on Prosper have no recourse against borrowers who may have used misleading information in their loan listings. Borrowers are never individually identified to lenders, and Prosper pursues all collection efforts on the lender's behalf. Thus, this setting offers a unique opportunity to further our understanding of how investors use unverifiable disclosures in decisions that have large economic consequences.

Analytical research on disclosures has typically focused on models where disclosures must be made truthfully. Early work in bargaining typically assumes signals are costless and verifiable (Grossman 1981; Milgrom 1981). However, since the seminal paper of Crawford and Sobel (1982), several analytical papers have explored scenarios in which the assumption that disclosures must be made truthfully is relaxed. In these so-called "cheap-talk" games, disclosures that are made may be false. Gigler (1994) shows that even when disclosures are unverifiable, the tension between proprietary costs and the wish to signal favorable information can make disclosures credible. That is, the cost associated with making the disclosure lends it credibility. However, in the setting of Prosper, one would not expect there to be proprietary costs associated with disclosing personal information for the purpose of obtaining a personal loan. Stocken (2000) considers a model in which a manager can make unverifiable disclosures to a potential investor. In this model the manager gives an unverifiable signal to an investor concerning the potential payoff of a project. In a single period game, no informative disclosures occur in equilibrium. In a repeated game, however, the manager will most likely disclose, and do so truthfully, as benefits exist to developing a reputation for telling the truth. While repeated interaction could produce credible disclosures on Prosper, the incidence of repeat borrowing is relatively low. During my sample period, 7 percent of borrowers obtained more than one loan through Prosper; however, less than 1 percent obtained more than two loans. Further, Stocken's (2000) result depends on both the number of interactions and the manager's discount factor being sufficiently high. A reading of the loan listings on Prosper indicates that many borrowers are financially distressed and already have large debts. This revealed preference for consumption over savings implies a low discount factor.

Models from the cheap-talk literature recognize that unverifiable disclosures are only relevant when agents' incentives are at least partially aligned (Farrell and Rabin 1996). However, evidence from both experiments and empirical studies demonstrates that people fail to fully account for conflicts of interest (Cain et al. 2005; Malmendier and Shanthikumar 2007). The tendency of people to rely on false or irrelevant information in decision making has been well established in the psychology literature. People behave as if their first reaction is to believe any information they are presented with (Gilbert 1991; Gilbert et al. 1993) and have difficulty ignoring irrelevant information in making decisions (Nisbett et al. 1981; Kahneman et al. 1982). Experimental research in marketing has produced results consistent with these findings. Carpenter et al. (1994) show that consumers value differentiating, but irrelevant, product attributes. Mandel and Johnson (2002) find changing only the background colors and images on a website influences product choices. Also, in psychology, Scharlemann et al. (2001) demonstrate subjects in a one-shot "trust" game exhibit more (potentially costly) cooperative behavior when their counterpart is represented by a picture of a smiling face. Overall, this stream of research suggests that lenders on Prosper would be influenced by the presence of unverifiable information in loan listings, especially given its prominent display in the listings (see Figures 1 and 2).

In related work in behavioral economics, Mullainathan et al. (2008) develop a model, in the spirit of the cheap-talk literature, that highlights how uninformative material can influence choice. Motivated by the psychology and marketing literature, they argue that rather than fully updating on new information, people think "coarsely" in that they partition potential outcomes into categories. The authors then demonstrate how this mental simplification strategy can result in useless information influencing choice, either through the misapplication of information within a partition, or by influencing the partition choice. Their model is consistent with results observed in experimental settings (for example, see Krueger and Clement 1994). A field experiment by Bertrand et al. (2010) also examines the effect of uninformative content on consumer choice. In loan offer letters sent to potential borrowers, the authors find that either including a picture of a smiling female, offering only one example of loans terms (versus several examples), or not suggesting a use for the loan increases offer acceptance by the same amount as a two-percentage point decrease in the interest rate of the loan. This result demonstrates that uninformative material can significantly affect behavior.

In sum, while traditional work in disclosure argues that unverifiable disclosures should be irrelevant, behavioral studies demonstrate that objectively uninformative content affects individual behavior. In the context of Prosper, if lenders are influenced by the voluntary, unverifiable disclosures made by borrowers in their loan listings, then I expect to see interest rates decreasing in the amount of disclosure. This leads to the following hypothesis:

H1: Interest rates are decreasing in the amount of voluntary, unverifiable disclosures in a loan listing.

If unverifiable disclosures in a loan listing are seen as convincing, then they should not only result in lower interest rates, but also greater bidding activity as well (Beaver 1968; Bamber 1986; Kim and Verrecchia 1991). That is, if these disclosures increase perceptions of quality regarding the loan listing, then I expect a listing with more disclosures to generate more bids. This prediction is consistent with work in auction theory that allows for entry of bidders (rather than assuming a fixed number of bidders). In this literature, it is costly to submit a bid. This cost is often interpreted as the cost of preparing the bid and processing information to learn what the object in question is worth. The number of entrants in an auction is decreasing in this cost (Samuelson 1985; McAfee and McMillan 1987; Levin and Smith 1994). If the unverifiable disclosures in a loan listing are perceived to be credible, then they should decrease the effort of learning the value of the loan, thus increasing the amount of bidding. This leads to my second hypothesis:

H2: The number of bids on a loan listing is increasing in the amount of voluntary, unverifiable disclosures in a loan listing.

Finally, I expect the relations in H1 and H2 to be stronger for loan listings by borrowers with relatively poor credit. Borrowers with good credit are likely able to obtain sufficient bids to fund their loan and a favorable rate by virtue of verifiable information alone (for example, their credit reports). Potential borrowers with poor credit will likely rely more heavily on the descriptive portion of the loan listing (that is, the section where they tell their personal story, which is unverifiable) in an effort to differentiate themselves from other competing borrowers with poor credit. Additionally, unverifiable disclosures may be more important for potential borrowers with poor credit quality because credit scores are based in part on the length of credit history. Therefore, a low credit score may reflect a dearth of verifiable information about a potential borrower. These predictions are formalized in the following hypotheses:

H3a: The relation between interest rates and the amount of voluntary, unverifiable disclosures in a loan listing is stronger for listings with relatively poor credit quality.

H3b: The relation between the number of bids and the amount of voluntary, unverifiable disclosures in a loan listing is stronger for listings with relatively poor credit quality.

Note that my measure of voluntary, unverifiable disclosure is a count of the number of specific items disclosed in the loan listing. While the specific content of what is revealed in a given disclosure is also likely to be important in determining its effect, I code only for the presence of a disclosure to increase objectivity. An indicator variable for the presence of a disclosure is a noisy proxy for its content. So to the extent the specific content of disclosures is important, my measure simply offers less powerful tests, biasing against finding a result. In additional analysis, I also investigate which types of disclosures have the greatest effect on lenders' decisions.

III. DATA

As outlined in Section I, the dataset of personal loan listings is collected from Prosper.com. All loans made through Prosper are three-year unsecured loans. Potential borrowers submit personal information to Prosper, enabling Prosper to verify their identity and obtain their credit reports. Prosper assigns a credit grade to each potential borrower based on his or her credit score.[7] Prosper also calculates a debt-to-income ratio (DTI) for each potential borrower by dividing the borrower's nonhousing debt payments (taken from their credit report) by his or her income. Income is self-reported by the borrower. Employment status,[8] length of employment, and occupation (chosen from a list) are also self-reported by potential borrowers.

After Prosper has obtained their credit information, potential borrowers can make loan listings by selecting the size of the loan they wish to obtain (maximum loan size is $25,000) and the maximum interest rate they are willing to pay (the maximum rate allowed is 35 percent). This information, along with their credit grade,[9] DTI ratio, employment status, length of employment, occupation, and stated income become part of the loan listing. Additionally, potential borrowers are encouraged to include in their loan listing a picture and additional personal information as to why they are good loan candidates in a free-form text field. This additional information often includes items such as the purpose of the loan (intended use of proceeds), current interest rates on other debts, explanations for poor credit grades, and monthly budgets. The picture and additional personal information are not verified by Prosper. Examples of loan listings are given in Figures 1 and 2.[10]

---

[7] AA = 760 and up, A = 720–759, B = 680–719, C = 640–679, D = 600–639, E = 560–599, HR (high risk) = 520–559. Persons with scores below 520 are not allowed to create a loan listing.

[8] Full-time, part-time, self-employed, retired, or not employed.

[9] Lenders have the ability to view a variety of credit information in addition to the credit grade, including number of accounts currently delinquent, amount delinquent, delinquencies in last seven years, public records in last 12 months, public records in last ten years, inquiries in last six months, first credit line, current credit lines, open credit lines, total credit lines, revolving credit balance, and bankcard utilization.

Once the borrower has made the loan listing, lenders may place bids on the listing. Lenders bid on loans by stating the amount of the loan they wish to fund (minimum of $50) and the minimum interest rate they are willing to receive (their reservation rate). Importantly, many different lenders may bid on and fund a loan listing. If, when the loan listing closes, the amount of money bid by lenders meets or exceeds the amount of the loan listing, then the listing becomes a loan. Winning bidders fund the loan in the amount of their bid and receive a note also equal to the amount of their winning bid. In the case that the total amount of bids exceeds the amount of the loan, the bidders with the lowest reservation rates are given priority in funding the loan. In this way, competition among lenders can lower the interest rate on a loan below the borrower's maximum acceptable rate.

Prosper makes money on this process by charging a closing fee to borrowers and a servicing fee to lenders. Penalties for default on Prosper loans are similar to those on other consumer debt. Delinquencies are reported to credit-reporting agencies, so borrowers' credit reports are adversely affected. Prosper also pursues collection efforts (through collections agencies) on behalf of the lenders. In no case can individual lenders pursue collection efforts themselves. Borrowers and lenders are identified to each other on the website only by screen names. Personal identities are not revealed.

The population of loan listings used in this study is all loan listings created on Prosper between February 12, 2007, and October 31, 2008. This period was selected because Prosper's informational policies remained constant over this time. In total, this includes 246,841 loan listings, 21,450 of which were successfully funded and 225,391 of which were not funded. The analysis that follows is based on a stratified random sample of 500 funded listings and 500 unfunded listings (1,000 listings in total).[11] I use a random sample rather than the entire population of listings because each loan listing must be read and hand-coded in developing the disclosure measure. I stratify over-funded and unfunded listings to ensure sufficient variation in each type of listing.

IV. RESEARCH DESIGN

Disclosure Measures

To evaluate the effect that voluntary, unverifiable disclosures have on the interest rate at which a loan listing funds, I must first develop a measure of such disclosures. To do this I grade each loan listing for the presence of specific voluntary and unverified information. One point is awarded for each item disclosed. Items scored are the purpose of the loan, income amount, income source, education, amount of other debt, interest rate on other debt, explanation for poor credit grade, listing of monthly expenses, and a picture of a person (presumably the borrower). All information I code is from the description section of the loan listing, which is not subject to verification.

The sum of all points awarded to a loan listing is its disclosure score (*DSCORE*). A summary of the definitions of the components of *DSCORE* is given in Panel A of Table 1, along with

---

[10] Some features of Prosper.com have changed since the time period examined in this study. All features described here relate to the operation of Prosper prior to November 2008. Many of the details of Prosper's operations during this time period are still available in the firm's SEC filings.

[11] Weights are not used in the following analysis; however, all inferences are robust to using sampling weights.

TABLE 1

Disclosure Score (*DSCORE*) Components

Panel A: Variable Definitions

Variable	Definition
Purpose	1 if purpose of loan given, 0 otherwise
Income	1 if income given, 0 otherwise
Inc Source	1 if income source given, 0 otherwise
Education	1 if education level given, 0 otherwise
Other Debt	1 if amount of other debt given, 0 otherwise
Other Debt Rate	1 if interest rate on other debt given, 0 otherwise
Poor Credit Expl	1 if explanation for poor credit grade given, 0 otherwise
Expenses	1 if monthly expenses listed, 0 otherwise
Picture	1 if picture of person included in listing, 0 otherwise

Panel B: Summary Statistics

	Unfunded			Funded			Difference in Means	
Variables	Obs.	Mean	Std. Dev.	Obs.	Mean	Std. Dev.	Diff.	Std. Err.
Purpose	500	0.87	0.34	500	0.93	0.25	−0.07***	(0.019)
Income	500	0.79	0.41	500	0.74	0.44	0.05+	(0.027)
Inc Source	500	0.30	0.46	500	0.39	0.49	−0.09**	(0.030)
Education	500	0.07	0.26	500	0.10	0.30	−0.02	(0.018)
Other Debt	500	0.12	0.32	500	0.17	0.37	−0.05*	(0.022)
Other Debt Rate	500	0.05	0.21	500	0.11	0.31	−0.06***	(0.017)
Poor Credit Expl	500	0.21	0.41	500	0.21	0.41	0.00	(0.026)
Expenses	500	0.80	0.40	500	0.71	0.45	0.09**	(0.027)
Picture	500	0.50	0.50	500	0.59	0.49	−0.09**	(0.031)

Panel C: *DSCORE* Frequencies

	Frequency		
DSCORE	Unfunded	Funded	Total
0	18	8	26
1	25	38	63
2	57	56	113
3	123	90	213
4	130	113	243
5	86	108	194
6	41	56	97
7	16	23	39
8	4	6	10
9	0	2	2
Total	500	500	1,000

+, *, **, *** $p < 0.10$, $p < 0.05$, $p < 0.01$, and $p < 0.001$, respectively (for two-tailed tests).
DSCORE for each loan listing in the sample equals the sum of the nine indicator variables listed in Panel A.

summary statistics in Panel B. Below I describe each of the components of the disclosure score in some detail.

Purpose: A point is awarded if the borrower states the intended use for the proceeds of the loan. If the purpose of the loan is debt consolidation, then I create an additional indicator variable, *DEBT*. Debt consolidation is the most commonly stated purpose for borrowing, and I expect loans with this purpose to be perceived as relatively less risky than other loans, because a borrower's financial situation is likely to improve if he or she can consolidate debt. Therefore, I include *DEBT* as a separate covariate outside of *DSCORE* in several of my model specifications.

Income Amount: Income amount refers to a disclosure of a specific monthly or yearly income number. This may include other income, such as that coming from a spouse or self-employment, which is not used in calculating the borrower's debt-to-income ratio (DTI). I include DTI as a separate control in the analysis. Because the borrower's self-reported income only indicates a $25,000 interval in which his or her income falls, a disclosure of a specific income value will provide incremental information to the lender. Thus a point is awarded for this disclosure.

Income Source: This disclosure specifies the source of the borrower's income. This may refer to additional sources of income beyond the mandatory job title given in the loan listing. It may also provide a more detailed description of the borrower's position. A point is not awarded for this disclosure if the borrower simply indicates the industry in which he or she is employed.

Education: A point is awarded if the borrower states in the listing the level of education he or she has achieved. However, statements such as "I need a loan to pay off student loans" or "pay for my last semester of tuition" do not earn points, as it is not clear if the borrower has completed or will complete the educational program.

Amount of other Debt: A point is awarded if the borrower reports outstanding balances of other debt.

Interest Rate on other Debt: A point is awarded if the listing reports the interest rate on at least one of the borrower's other debts. A specific interest rate must be stated. For example, simply stating that the borrower wants to use the loan to consolidate other high-interest debt does not earn a point without explicitly stating at least one rate.

Explanation of Poor Credit: A point is awarded if the borrower explains why his or her credit grade is low. The statement must be specific with respect to the reason the credit grade is low. For example, the statement "I need the loan because I have fallen behind on my mortgage payments" would not earn a point by itself, even though this is likely at least partially the source of the poor credit grade. Stating "I was injured in a car accident and have been unable to work, thus have trouble keeping up with bills" would earn a point.

Monthly Expenses: A point is awarded if the borrower lists their monthly expenses, for example, a budget.

Picture: A point is awarded if the listing includes a picture of a person, independent of who the picture represents.

Figures 1 and 2 offer examples of these disclosures. The loan listings in Figures 1 and 2 earn a point for the *Picture* disclosure. Likewise, both listings earn a point for stating the purpose of the loan, which is "for a business start up" in Figure 1 and "to payoff [sic] two very high interest credit cards" in Figure 2. The loan listing in Figure 2 also includes *Explanation of Poor Credit* as "credit issues due his hospitilization [sic]," *Income,* and *Monthly Expenses*. In particular, note that the listing in Figure 2 discloses income that would not be used in calculating the borrower's DTI.

Panel B of Table 1 reports summary statistics for the components of the disclosure score (*DSCORE*) in the sample. As noted previously, each element of the score is an indicator variable taking a value of 1 if the disclosure is present in the loan listing, and 0 otherwise. Most elements of the disclosure score display significant variation, although *Purpose, Education,* and *Other Debt Rate* have relatively low variation.

Panel B of Table 1 also reports that, for the nine disclosure components, disclosure frequency is greater for funded loans in six components, and five of these differences are statistically significant. Panel C of Table 1 reports the frequency of different levels of *DSCORE*. The median number of disclosures across all loan listings is 4. Successfully funded loans have a higher frequency than unfunded loans in each *DSCORE* category above 4. This preliminary evidence suggests lenders consider these unverifiable disclosures in the bidding process.

Control Variables

The variables used to control for other likely sources of variation in the rate at which a loan listing is funded and the number of bids it receives are auto-funding, maximum interest rate, loan amount, credit grade, homeownership, DTI, two-year Treasury bond yield, group membership, and prior loan performance. Each of these variables is described next.

Auto-Funding (AUTOF): A listing with automatic funding is closed as soon as the requested amount is met by bidders, so that additional bidders cannot bid down the rate once the loan is fully funded. This is an option for borrowers who want to fund a loan quickly. I expect auto-funded loans to have higher interest rates, as there is less opportunity for competition among bidders. This variable is an indicator variable taking value of 1 if the loan uses auto-funding, and 0 otherwise.

Maximum Interest Rate (MAXR): The borrower sets the maximum interest rate above which bids for funding the loan will not be accepted. It is not clear what effect this variable will have on the final rate of a loan. While *MAXR* places a cap on how high the rate can be, higher values could attract more bids, pushing the final interest rate lower.

Loan Amount (LAMT): Loan amount is the natural logarithm of the principal amount of the loan requested. I expect larger loans to have higher interest rates because larger payments should increase the risk of default. Larger loans should also attract more bids, because, holding bid size equal, it takes more bids to fund the loan.

Credit Grade (CRDG): The credit grade assigned to the borrower by Prosper is based on the borrower's credit score (see footnote 7). Grades range from AA (best) to HR or High Risk (worst). For the purposes of analysis, grades are assigned an integer value ranging from 1 to 7, with 1 reflecting the best credit grade (AA). I expect interest rates to be increasing with the credit grade.[12]

Homeownership (HOME): This variable indicates whether the borrower is a homeowner, as indicated by an active mortgage loan on the borrower's credit report. The effect of homeownership on the funded interest rate is not clear. Homeowners may be perceived as being more financially stable and may have greater access to other funding by using their house as collateral. Alternatively, the greater expense and inflexibility associated with a mortgage payment may increase risk. This variable is an indicator variable taking value of 1 if homeownership has been verified, and 0 otherwise.

Debt-to-Income Ratio (DTI): The debt-to-income ratio is the borrower's nonhousing debt payments, including both principal and interest components as taken from their credit report, divided by self-reported income. I expect interest rates to be increasing in DTI.

Bond Yield (BOND): This variable is the two-year Treasury bond yield on the date the listing was posted.[13] Listings fund quickly, usually within seven days. Even though all Prosper loans have three-year maturities, I use the two-year bond as there are no prepayment penalties, so I expect some loans to be paid back early. I expect interest rates charged on loans to increase with bond yields, as the opportunity cost of lending is greater. Additionally, bond yields are generally increasing with expected inflation, so higher bond yields are also a proxy for inflation risk, which should increase the funded interest rate.

---

[12] Conclusions from the analysis are unchanged if I use an array of indicator variables for credit score in place of the index variable *CRDG*.

[13] Taken from http://www.federalreserve.gov/releases/h15/data.htm

Group Membership (GROUP): Groups on Prosper are collections of people with a common interest, including professional, ethnic, religious, geographic, or athletic. The concept is that a group whose members consistently make on-time loan payments will develop a reputation, allowing the group's members to attract more bids and lower interest rates to their loan listings. Likewise, the social pressure of maintaining the group's reputation could reduce the likelihood of default for borrowers in the group. However, groups do not guarantee the loans of their members and members are in no way jointly liable for the loans of other group members. Several contemporaneous working papers show membership in a group of affiliated members on Prosper may affect the success of loan listings (Freedman and Jin 2008; Lin et al. 2009). Therefore, I include a control variable indicating group membership.

Prior Loan Performance (PR_G and PR_B): During my sample period, about 7 percent of borrowers had obtained loans previously through Prosper. Because prior loans are visible to lenders, I include control variables indicating the presence and performance of a prior loan. I expect that having either a loan on which all payments are current or having a fully paid prior loan (*PR_G*) to decrease the interest rate on a listing, while having a loan in default or with late payments (*PR_B*) should increase the interest rate on a listing.

Panel A of Table 2 reports summary statistics for all regression variables. *DSCORE* has a median of 4 of a possible of 9 for both funded and unfunded listings. The mean of *DSCORE* is slightly higher for funded loans at 3.95, compared to 3.70 for unfunded listings. Panel B of Table 2 gives the correlations between all regression variables.[14] For funded loans, the Pearson correlation of 0.203 between *RATE* and *DSCORE* is statistically significant, reflecting a positive relation between *RATE* and *DSCORE* before controlling for any other variables. Although this positive association is contrary to the hypothesis that the interest rate charged will be decreasing in disclosures, *DSCORE* is also strongly correlated with *CRDG*, the borrower's credit score, which may explain this result, as *CRDG* has a strong positive correlation with *RATE*. Indeed, the partial correlation between *RATE* and *DSCORE*, holding *CRDG* constant, is significantly negative at −0.084. The positive correlation between *DSCORE* and *CRDG* is consistent with the argument in Section II that the descriptive portion of the loan listing is relatively more important for borrowers with relatively poor credit.

Model

To test the effect of unverifiable disclosures on the interest rate at which a loan is funded (H1), I use a Tobit regression of the interest rate at which a loan listing is funded on the disclosure score and control variables. If lenders perceive the unverifiable disclosures in the loan listings as credible, then I expect to see the interest rate decreasing in the disclosure score. For unfunded loans, the interest rate limit is set at 35 percent, the maximum allowable rate. This assumes all loans would be funded at some interest rate if rates were allowed to exceed 35 percent. As noted in Section III, the sample has 500 funded loans (uncensored) and 500 unfunded loans (right-censored at $RATE \geq 0.35$). As previously described, the control variables used are auto-funding, maximum interest rate, loan amount, credit grade, homeownership, DTI, two-year Treasury bond yield, group membership, and prior loan performance. That is:

$$RATE_i = f(\beta_0, \beta_1 AUTOF_i, \beta_2 MAXR_i, \beta_3 LAMT_i, \beta_4 CRDG_i, \beta_5 HOME_i, \beta_6 DTI_i, \beta_7 BOND_i,$$

---

[14] All Variance Inflation Factors (VIFs) associated with the independent variables used in subsequent models are less than 2, indicating multicollinearity is unlikely to pose a problem (Menard 1995; Kennedy 2008).

Bold indicates significance at the 10 percent level or better.

[a] *RATE* is the interest rate at which the loan funded. *BIDS* is the number of bids on the loan divided by the number of days the loan listing was open, rounded to the nearest integer. *AUTOF* is an indicator variable for auto-funding. *MAXR* is the maximum interest rate that the borrower will accept for his loan listing. *LAMT* is the natural log of loan principal amount. *CRDG* is borrower's credit score. *HOME* is an indicator variable for homeownership. *DTI* is borrower's debt-to-income ratio. *BOND* is the two-year Treasury bond yield on loan listing date. *GROUP* is an indicator variable for membership in a Prosper Group. *PR_G* is an indicator variable for having a prior Prosper loan that was paid off. *PR_B* is an indicator variable for having a prior Prosper loan that defaulted. *DEBT* is an indicator variable for the borrower claiming that the purpose of the loan is debt consolidation/refinancing. *DEFAULT* is an indicator variable for the loan resulting from the listing eventually defaulting. *DSCORE* is the borrower's disclosure score (see Table 1).

[b] Pearson correlations are below the diagonal, Spearman correlations are above.

$$\beta_8 GROUP_i, \beta_9 PR\_G_i, \beta_{10} PR\_B_i, \beta_{11} DSCORE_i) + \varepsilon_i \qquad (1)$$

where:

$RATE$ = interest rate at which the loan was funded;
$AUTOF$ = indicator variable, taking value of 1 if loan used auto-funding, 0 otherwise;
$MAXR$ = maximum interest rate the borrower will accept for his or her loan listing;
$LAMT$ = natural logarithm of principal amount of the loan;
$CRDG$ = borrower's credit score; takes integer values 1 through 7, with 1 being best score (or AA, see footnote 7);
$HOME$ = indicator variable, taking value of 1 if borrower is homeowner, 0 otherwise;
DTI = borrower's debt-to-income ratio;
$BOND$ = yield on two-year Treasury bond on date loan listing was posted;
$GROUP$ = indicator variable, taking value of 1 if borrower is a member of a Prosper group, 0 otherwise;
PR_G = indicator variable, taking value of 1 if the borrower has a prior loan that has been paid off or is current at the time of the listing, 0 otherwise;
PR_B = indicator variable, taking value of 1 if the borrower has a prior loan that defaulted or has late payments at the time of the listing, 0 otherwise; and
$DSCORE$ = borrower's disclosure score (see Table 1).

The coefficient of primary interest is β_{11}. Alternatively, I estimate this model using each level of disclosure, rather than the index variable *DSCORE*.

I use a Poisson regression to test the effect of unverifiable disclosures on the number of bids a loan listing receives (H2). For this model, the dependent variable is the number of bids per day a listing receives (*BIDS*). Formally, I define *BIDS* as the number of bids on a loan divided by the number of days the loan listing was open, rounded to the nearest integer. If the lenders perceive the additional information provided in the unverifiable disclosures represented in *DSCORE* as credible, I expect to see *BIDS* increasing in *DSCORE*, as the lender's assessment of the loan listing is improved. Note that *BIDS* is not censored for unfunded loans. I use a Poisson regression due to the count nature of the *BIDS* variable.[15] Thus, the second model is:

$$BIDS_i = g(\beta_0, \beta_1 AUTOF_i, \beta_2 MAXR_i, \beta_3 LAMT_i, \beta_4 CRDG_i, \beta_5 HOME_i, \beta_6 DTI_i, \beta_7 BOND_i, \\ \beta_8 GROUP_i, \beta_9 PR\_G_i, \beta_{10} PR\_B_i, \beta_{11} DSCORE_i) + \varepsilon_i \qquad (2)$$

Control variables are as defined in Model (1). Again, the coefficient of primary interest is β_{11}. I also estimate this model using each level of disclosure, rather than the index variable *DSCORE*.

To test H3a and H3b, I define a new variable, *POOR*, as an indicator variable taking a value of 1 if *CRDG* is greater than or equal to 5.[16] Thus, *POOR* is an indicator for loan listings where the borrower has relatively poor credit. I then re-estimate Models (1) and (2) adding *POOR* and the interaction of *POOR* with all other independent variables. The coefficient of primary interest is that on the interaction *DSCORE***POOR*.

---

[15] Results are robust to using a zero-inflated Poisson or negative binomial regression.

[16] I partition around $CRDG = 5$, as 5 is the median value of this variable. Defining *POOR* to indicate $CRDG \geq 5$ creates the most equal partitions. However, inferences from tests are unchanged if I define *POOR* to indicate $CRDG \geq 4$. Inferences are again unchanged if I define *POOR* to indicate $CRDG \geq 6$ in the Poisson models; however, the interaction term $DSCORE * POOR$ becomes statistically insignificant in the Tobit models under this definition.

+, *, **, *** $p < 0.10$, $p < 0.05$, $p < 0.01$, and $p < 0.001$, respectively (for two-tailed tests).

Tobit regression of interest rate at which loan was funded on disclosure score and control variables. Interest rate limit for unfunded loans is set at 35 percent, the maximum allowable rate. The sample has 500 funded loans (uncensored) and 500 unfunded loans (right-censored at $r \geq 0.35$). Standard errors in parentheses.

Dependent variable is *RATE*.

[a] *RATE* is the interest rate at which the loan funded. *AUTOF* is an indicator variable for auto-funding. *MAXR* is the maximum interest rate that the borrower will accept for his loan listing. *LAMT* is the natural log of loan principal amount. *CRDG* is borrower's credit score. *HOME* is an indicator variable for homeownership. *DTI* is borrower's debt-to-income ratio. *BOND* is the two-year Treasury bond yield on loan listing date. *GROUP* is an indicator variable for membership in a Prosper Group. *PR_G* is an indicator variable for having a prior Prosper loan that was paid off. *PR_B* is an indicator variable for having a prior Prosper loan that defaulted. *DEBT* is an indicator variable for the borrower claiming that the purpose of the loan is debt consolidation/refinancing. *DSCORE* is the borrower's disclosure score (see Table 1).

V. RESULTS

Table 3 presents the results for Model (1). The sign on the *DSCORE* coefficient is negative and statistically significant, consistent with H1. This suggests that the voluntary, unverifiable disclosures in a loan listing do affect the loan's interest rate. The coefficient on *DSCORE* of

−0.0127 indicates each additional disclosure is associated with a reduction in the loan's interest rate of 1.27 percentage points. Thus, all else equal, a loan listing with a *DSCORE* at the 75th percentile (*DSCORE* of 5) could expect to obtain an interest rate 2.54 percentage points lower than a loan listing with a *DSCORE* at the 25th percentile (*DSCORE* of 3).

The signs on the coefficients of the control variables are largely as expected. All but *HOME* and *PR_B* are statistically significant. The lack of significance on *PR_B* is surprising. While the positive and significant coefficient on *PR_G* indicates that lenders give lower rates to borrowers with good payment histories on prior loans, the lack of significance on *PR_B* suggests lenders do not punish borrowers for late payments or defaults on prior loans. Lenders may choose to ignore this negative information in the listing, or it may be subsumed by the other credit information in *CRDG*. Alternatively, lenders may believe that all borrowers on Prosper are likely to have poor payment histories, so they do not update their beliefs after observing late payments. As expected, the coefficient on *DEBT* is negative, indicating borrowers who state the purpose of their loan is debt consolidation receive a significantly lower rate than other borrowers. This is again consistent with unverifiable disclosures in the loan listings affecting lender behavior. The negative and significant coefficient on *BOND* is also surprising. This indicates that lower two-year bond yields are associated with higher loan rates. This may reflect lenders' heightened concern regarding the creditworthiness of borrowers who seek financing through Prosper when bank loan rates are low.

In untabled analysis, I estimate Model (1) using levels of the *DSCORE* variable in the regression, rather than the index variable. Every level of *DSCORE* is negatively associated with interest rates, consistent with the result from Table 3 that interest rates are decreasing with disclosure. While the increase in the magnitude of coefficients as the number of disclosures increases is not monotonic, the general trend is that more disclosures are associated with more negative coefficients. F-tests reveal the change in interest rate for an additional disclosure is relatively constant over different levels of disclosure. However, the decrease in rate for an increase from four to five disclosures is significantly greater than the change in rate for an increase from three to four disclosures. The impact of disclosures on rate is not statistically significant until five disclosures are present in the listing.

I also estimate several variations of Model (1) to demonstrate that the results are robust to alternative ways of controlling for the credit quality of potential borrowers. First, I replace the variable *CRDG*, which takes values of 1 to 7, with each value corresponding to a specific credit grade, with an array of dummy variables for each category of credit grade. Using *CRDG* to control for credit worthiness could be problematic because it equalizes the effect of credit grade on interest rate across every credit category. This could introduce a bias in *DSCORE* if interest rates are increasing in credit grade but at a decreasing rate, as *DSCORE* is also associated with credit grades. However, results are largely unchanged when using dummy variables to control for credit grades in a more general way, with the coefficient on *DSCORE* being −0.0123 and remaining significant at the 0.1 percent level. Second, I add all additional employment and credit report data that are available to lenders, as outlined in footnotes 8 and 9, as controls in the analysis. If these additional credit data are negatively associated with interest rates and positively associated with disclosures, then omitting it would introduce a negative bias to the *DSCORE* coefficient. Again, however, the results are robust to the inclusion of these additional controls, with the coefficient on *DSCORE* being −0.0120 and statistically significant at the 0.1 percent level.

Table 4 presents the results for regression Model (2). The coefficient on *DSCORE* is positive and statistically significant, indicating that more voluntary disclosures increase the bidding activity on a loan, consistent with H2. Again, this suggests that lenders consider the voluntary, unverifiable disclosures in the loan listings in their investment decisions. The coefficient on *DSCORE* of 0.08 in this regression indicates, all else equal, that an additional disclosure in the loan listing is associated with an 8 percent increase in the number of bids on the listing. The coefficient on *DEBT* is insignificantly

Poisson regression of number of bids per day listing was open on disclosure score and control variables. Robust standard errors in parentheses.

Dependent variable is *BIDS*.

[a] *BIDS* is the number of bids on the loan divided by the number of days the loan listing was open, rounded to the nearest integer. *AUTOF* is an indicator variable for auto-funding. *MAXR* is the maximum interest rate that the borrower will accept for his loan listing. *LAMT* is the natural log of loan principal amount. *CRDG* is borrower's credit score. *HOME* is an indicator variable for homeownership. *DTI* is borrower's debt-to-income ratio. *BOND* is the two-year Treasury bond yield on loan listing date. *GROUP* is an indicator variable for membership in a Prosper Group. *PR_G* is an indicator variable for having a prior Prosper loan that was paid off. *PR_B* is an indicator variable for having a prior Prosper loan that defaulted. *DEBT* is an indicator variable for the borrower claiming that the purpose of the loan is debt consolidation/refinancing. *DSCORE* is the borrower's disclosure score (see Table 1).

different from zero, indicating that, while borrowers stating loan consolidation as the purpose of their loan may receive lower rates, they do not generate more bidding activity on their listings.

As with Model (1), in untabulated results I estimate Model (2) with categories of *DSCORE* rather than the index variable. More extreme disclosure categories lack significance, perhaps due to limited power in these categories (see Table 1, Panel C). Disclosures in the listings do not affect the bidding on a listing until five disclosures are present. While the effect of an additional disclosure is

Poisson regression of number of bids per day listing was open on disclosure score and control variables. Robust standard errors in parentheses.

Dependent variable is *BIDS*.

[a] *BIDS* is the number of bids on the loan divided by the number of days the loan listing was open, rounded to the nearest integer. *AUTOF* is an indicator variable for auto-funding. *MAXR* is the maximum interest rate that the borrower will accept for his loan listing. *LAMT* is the natural log of loan principal amount. *CRDG* is borrower's credit score. *HOME* is an indicator variable for homeownership. *DTI* is borrower's debt-to-income ratio. *BOND* is the two-year Treasury bond yield on loan listing date. *GROUP* is an indicator variable for membership in a Prosper Group. *PR_G* is an indicator variable for having a prior Prosper loan that was paid off. *PR_B* is an indicator variable for having a prior Prosper loan that defaulted. *DEBT* is an indicator variable for the borrower claiming that the purpose of the loan is debt consolidation/refinancing. *DSCORE* is the borrower's disclosure score (see Table 1). *POOR* is an indicator variable for $CRDG \geq 5$.

and 0.08 when including all additional creditworthiness controls, outlined in footnotes 8 and 9. Both are statistically significant at the 0.1 percent level. In addition, all results from subsequent analysis in this paper are robust to including these additional control variables. For parsimony, I only discuss results using *CRDG* as the credit quality control in subsequent analysis.

The results from the models testing H3a and H3b are presented in Table 5 and Table 6, respectively. In Table 5 the coefficient on the interaction *DSCORE* $*$ *POOR* of –0.0139 is statistically significant, indicating that an additional disclosure reduces a listing's interest rate by 1.39 percentage points more for borrowers with relatively poor credit. This is consistent with H3a. Table 6, consistent with H3b, shows that the coefficient on the interaction *DSCORE*$*$*POOR* is 0.1821, which is statistically significant. This indicates an additional disclosure increases bidding activity by 18.21 percent more for borrowers with relatively poor credit. Collectively, these results indicate that unverifiable disclosures are relatively more important for borrowers with relatively poor credit.

VI. ALTERNATIVE SPECIFICATIONS

In this section, I test the robustness of my results. First, I use a two-step model, rather than a Tobit model, to analyze separately whether a loan is funded and, if it is funded, which interest rate it receives. Next, I allow for the possibility that certain components of my disclosure measure may be correlated with information that is verified elsewhere in the loan listing. I separate from my disclosure measure those components that in limited instances may be verified in other sections of the loan listing to ensure I am measuring only the effect of truly unverifiable items in influencing lender behavior.

Table 7 shows the results of the two-step model. First, I estimate a probit model, regressing an indicator for a listing successfully funding on *DSCORE* and control variables. The results show that, for the average listing, an additional unverifiable disclosure increases the likelihood of funding by 3.28 percent. Next, for the subsample of successfully funded loans, I regress the actual interest rate on *DSCORE* and control variables. This shows that, given a loan is funded, an additional disclosure decreases the interest rate by 0.22 percentage points. Finally, I estimate a Heckman two-step model, where the inverse-Mills ratio from the funding equation is added to the rate regression to control for selection effects. I omit *GROUP* from the rate regression in the Heckman model to avoid identification only through nonlinearities. I use this as the identifying variable because group membership, while having a large effect on whether the loan receives enough bids to fund (as seen in the selection model), may have little direct impact on the rate of the loan.[17] Results from the Heckman model show that an additional disclosure decreases the interest rate on a loan by 0.31 percentage points.

Table 8 shows the results of Models (1) and (2) with the *DSCORE* disclosure index replaced with an array of indicator variables for each specific disclosure included in the index. Many individual disclosures do not have a statistically significant effect when considered in isolation. *Purpose*, *Other Debt Rate*, and *Poor Credit Expl* appear the most important in determining interest rates, while *Purpose, Other Debt*, and *Poor Credit Expl* have the greatest effect on bidding activity.

In limited instances Prosper may verify other borrower-provided information in the loan listing, such as income, employment, or occupation. While the information I code in developing *DSCORE* comes only from the descriptive portion of the loan listing, which is not subject to verification, this information is likely to be consistent with the information provided by the borrower elsewhere in the listing. Thus, these disclosures could be considered at least partially verified. Therefore, to ensure that lenders' responses to *DSCORE* are reflecting reliance on unverifiable information, I

---

[17] The fact that I am able to control for all information in a loan listing available to potential lenders mitigates the concern of selection bias. Identifying an exogenous instrument is difficult in this setting, as only information potentially relevant in the lending decision is likely to be included in the loan listing. Note results from the Heckman model are robust to not excluding a variable in the second stage, which may be a preferred specification when reasonable exclusion restrictions do not exist (Li and Prabhala 2007).

[a] *RATE* is the interest rate at which the loan funded. *BIDS* is the number of bids on the loan divided by the number of days the loan listing was open, rounded to the nearest integer. *AUTOF* is an indicator variable for auto-funding. *MAXR* is the maximum interest rate the borrower will accept for his loan listing. *LAMT* is the natural log of loan principal amount. *CRDG* is borrower's credit score. *HOME* is an indicator variable for homeownership. *DTI* is borrower's debt-to-income ratio. *BOND* is the two-year Treasury bond yield on loan listing date. *GROUP* is an indicator variable for membership in a Prosper Group. *PR_G* is an indicator variable for having a prior Prosper loan that was paid off. *PR_B* is an indicator variable for having a prior Prosper loan that defaulted. *DSCORE* is the borrower's disclosure score (see Table 1). *Purpose–Picture* are individual components of *DSCORE* (see Table 1). *D_VER* is a subset of *DSCORE* (the sum of *Income*, *Inc Source*, *Other Debt*, and *Other Debt Rate*). *D_UNV* is another subset of *DSCORE* (the sum of *Purpose*, *Education*, *Poor Credit Expl*, *Expenses*, and *Picture*).

both magnitude and statistical significance. This offers additional evidence that borrowers respond to truly unverifiable information in loan listings.

VII. LOAN OUTCOME ANALYSIS

Given that unverifiable disclosures in loan listings significantly influence the decisions of lenders, a natural extension is to examine how these disclosures relate to loan performance. To accomplish this, I perform a probit regression of an indicator for eventual loan default on *DSCORE* and control variables. Table 9 shows the results of this model, with average marginal effects reported. This analysis is limited to listings that resulted in loans. The size of the loan strongly predicts future default, as does having a prior loan with poor performance. Of all control variables, only having a prior loan with current payments is significantly associated with a lower risk of future default. Interestingly, rate does not predict default. *DSCORE,* however, has a strong negative association with future defaults. An additional disclosure is associated with a 5.37 percent less chance of future default. Partitioning *DSCORE* into two components, as in Table 8, demonstrates that it is the most unverifiable of the disclosures that are driving this result. Thus, lenders' reliance on unverifiable disclosures in the loan listings appears to be validated in an *ex post* sense.

VIII. CONCLUSION

This study analyzes the impact of voluntary, unverifiable disclosures with a unique dataset of peer-to-peer loans. This setting allows for more powerful tests of unverifiable disclosures than are possible with publicly traded firms. The results indicate that such disclosures influence lenders by both decreasing the interest rate charged and increasing the bidding activity on a loan. Additional analysis shows the effect of these disclosures is stronger for borrowers with relatively poor credit. Further, unverifiable disclosures are negatively associated with future loan defaults.

Dependent variable is *DEFAULT*.

[a] *DEFAULT* in an indicator variable for the loan resulting from the successful listing eventually defaulting. *AUTOF* is an indicator variable for auto-funding. *MAXR* is the maximum interest rate that the borrower will accept for his loan listing. *LAMT* is the natural log of loan principal amount. *CRDG* is borrower's credit score. *HOME* is an indicator variable for homeownership. *DTI* is borrower's debt-to-income ratio. *BOND* is the two-year Treasury bond yield on loan listing date. *GROUP* is an indicator variable for membership in a Prosper Group. *PR_G* is an indicator variable for having a prior Prosper loan that was paid off. *PR_B* is an indicator variable for having a prior Prosper loan that defaulted. *RATE* is the interest rate at which the loan funded. *DSCORE* is borrower's disclosure score (see Table 1). *D_VER* is a subset of *DSCORE* (the sum of *Income*, *Inc Source*, *Other Debt*, and *Other Debt Rate*). *D_UNV* is another subset of *DSCORE* (the sum of *Purpose*, *Education*, *Poor Credit Expl*, *Expenses*, and *Picture*).

These results can be interpreted as being consistent with a desire of borrowers to develop a reputation for truth telling in their disclosures so that they can continue to benefit from using these disclosures in future loan listings (Stocken 2000). However, this interpretation requires the possibility of repeated borrowing, which is observed only to a limited degree in the data. The results are also consistent with work in psychology and behavioral economics that shows objectively uninformative material can influence individual choice. Developing an appreciation for how individuals value and react to these types of disclosures is important in understanding and predicting the behavior of market participants.

Accrual Quality, Realized Returns, and Expected Returns: The Importance of Controlling for Cash Flow Shocks

Maria Ogneva
Stanford University

ABSTRACT: This paper develops a simple methodology based on the earnings response coefficient framework that allows decomposing realized returns into cash flow shocks and returns excluding cash flow shocks. I find that stocks with poor (good) accrual quality were on average subject to relatively lower (higher) cash flow shocks over the past 37 years. These lower (higher) cash flow shocks offset the higher (lower) expected returns of poor (good) accrual quality firms. After excluding cash flow shocks, future realized returns are negatively associated with accrual quality. The premiums pertaining to accrual quality are both statistically and economically significant in standard asset-pricing tests when cash flow shocks are excluded by firm-specific return decomposition. Overall, this paper provides evidence on the existence of a priced accrual quality risk factor, and underscores the importance of controlling for cash flow shocks in asset-pricing tests that use realized returns.

Keywords: *accounting quality; asset pricing; cash flow shocks; cost of equity.*

I. INTRODUCTION

There is an ongoing debate as to whether the quality of accounting information influences firms' cost of equity capital. Much of the debate centers around the existence of a priced risk factor related to the quality of accruals. In an influential set of papers, Francis et al. (2004, 2005; hereafter, FLOS) argue that accrual quality affects the cost of equity.[1] FLOS base their

I thank K. R. Subramanyam, my dissertation chair, for his continuous support and guidance in the development of this paper. I am thankful to Paul Zarowin (editor) and two anonymous referees for their insightful comments and suggestions. I am also grateful for support from the members of my dissertation committee, including Randy Beatty, Mark DeFond, Christopher Jones, and especially Rebecca Hann. This paper benefited from the helpful comments and suggestions from Mary Barth, Nerissa Brown, Mei Cheng, Yaniv Konchitchki, Charles Lee (the discussant), Siqi Li, Hai Lu, Steven Monahan, Suresh Nallareddy, Per Olsson, Joe Piotroski, Tatiana Sandino, Joe Weber, Biqin Xie, Jieying Zhang, and participants at the workshops in University of Southern California, Stanford University, University of Pennsylvania, Massachusetts Institute of Technology, the 2008 Stanford Accounting Summer Camp, and the UNC/Duke Fall Camp. I am grateful to the Deloitte Foundation and to the Michelle R. Clayman Faculty Scholar endowment for financial support.

Editor's note: Accepted by Paul Zarowin.

[1] Throughout the paper, I use "cost of equity" and "expected return" interchangeably.

conclusions in part on a significant positive correlation between the returns on *AQ Factor* (the accrual quality factor) and contemporaneous stock returns.[2] However, using conventional two-stage asset-pricing tests (e.g., Fama and MacBeth 1973; hereafter, Fama-MacBeth), Core et al. (2008; hereafter, CGV) show that the loadings on *AQ Factor*, although positive on average, do not explain the cross-sectional variation in returns. In addition, CGV document that accrual quality, as a characteristic, does not predict future (one-year-ahead) realized returns. Taken together, the findings in CGV are inconsistent with accrual quality being priced by the market. Resolving the debate on the existence of a priced risk factor related to accrual quality is important given the large number of studies that implicitly or explicitly rely on the existence of *AQ Factor*.[3]

In this paper, I argue that CGV are unable to find an association between accrual quality and future realized returns because their inverse measure of accrual quality—the residual accrual volatility measure proposed by Dechow and Dichev (2002; hereafter, the *DD Measure*)—is negatively correlated with future cash flow shocks; that is, firms with low (high) accrual quality experience more negative (positive) cash flow shocks in the future.[4] Due to this correlation, the higher (lower) expected returns associated with poor (good) accrual quality firms are systematically offset by negative (positive) cash flow shocks, thereby leading to no association between future realized returns and accrual quality.

Prior research provides evidence that indirectly supports the conjectures above. Both FLOS and CGV use *DD Measure* to measure accrual quality. The *DD Measure* is estimated as the standard deviation of the residuals from a regression of working capital accruals on past, current, and future operating cash flows, such that *higher* levels of *DD Measure* represent *lower* accrual quality. The *DD Measure* is correlated with several characteristics that are likely to be associated with future cash flow news. For example, high *DD Measure* (i.e., low accrual quality) stocks that have higher sales growth in the past (Doyle et al. 2007), are likely to have higher bankruptcy risk due to a high frequency of losses (Dechow and Dichev 2002), and have more volatile earnings and sales (Dechow and Dichev 2002). Each of these characteristics has been linked to systematic future underperformance in the stock market (Lakonishok et al. 1994; Dichev 1998; Mohanram 2005), possibly as a result of adverse cash flow news.

To detect a premium on accrual quality, I perform asset-pricing tests that use a novel measure of expected returns—realized returns exclusive of cash flow shocks. I rely on the earnings response coefficient framework to estimate the cash flow shock portion of realized returns. A cash flow shock is a return arising from a revision in the expectation of the entire stream of future cash flows, which can be measured as the return associated with an earnings surprise. I estimate cash flow shocks as fitted values from regressions of realized returns on earnings surprises. These regressions vary along two dimensions: the assumption of a linear versus nonlinear relation between returns and earnings surprises, and the choice of a cross-sectional versus time-series research design. The linear cross-sectional (firm-specific time-series) return decomposition is expected to be the least (the most) powerful at identifying returns associated with earnings surprises (e.g., Lipe et al. 1998).

---

[2] The conclusions in FLOS (2004, 2005) are based on multiple tests that, in addition to *AQ Factor*, employ earnings-to-price ratios, betas, and implied cost-of-equity estimates to proxy for cost of equity. The results based on these alternative proxies are generally consistent with low accrual quality being penalized with higher cost of equity.

[3] For example, studies that use the loadings on *AQ Factor* to proxy for accounting quality include Ecker et al. (2006), Chen et al. (2007), Kravet and Shevlin (2010), Krishnan et al. (2008), Kim and Venkatachalam (2011), Ecker (2009), Bhattacharya et al. (2009), and Chang et al. (2009).

[4] In the finance literature (e.g., Campbell 1991), the term "cash flow shock" describes the return resulting from a revision in expectation of future benefits accruing to equity holders. The earnings response coefficient studies in the accounting literature (e.g., Kormendi and Lipe 1987) use earnings surprises to proxy for such revisions.

I start my empirical analyses by replicating CGV's findings for a sample of 92,145 firm-year observations with returns from April 1971 to March 2008.[5] Unlike CGV, I lag *DD Measure* by one year to prevent the look-ahead bias in asset-pricing tests.[6] First, I confirm CGV's "non-result" for my sample period. In particular, *DD Measure* does not predict future stock returns either at the individual stock level or at the portfolio level. Similarly, stocks with higher loadings on *AQ Factor*, the accrual quality factor based on *DD Measure*, do not earn significantly higher returns at the portfolio level.

Next, I decompose total realized returns into cash flow shocks and returns that exclude cash flow shocks. The results of the decomposition confirm that stocks with poor accrual quality (high *DD Measure*) experience significantly more negative cash flow shocks in the near future. The result is robust to the choice of a time-series or cross-sectional research design and to different nonlinearity assumptions.

Finally, I perform asset-pricing tests using returns that exclude cash flow shocks. As in CGV, the tests use either *DD Measure* or the loading on *AQ Factor* (*AQ Factor* beta) and are performed either at individual stock or portfolio level. The results are mixed. *DD Measure* as a characteristic is, by itself, a significant predictor of future returns excluding cash flow shocks. However, the premium on *DD Measure* (i.e., the regression coefficient on the decile rank of the *DD Measure*) is reduced after controlling for the three Fama-French characteristics of beta, market value of equity, and book-to-market. It remains statistically significant only in the test that relies on the firm-specific time-series return decomposition, the most powerful research design. The premium from the latter test is also economically significant, implying a 3.24 percent difference in annualized returns between stocks in the highest and the lowest *DD Measure* deciles.

The premium on *AQ Factor* (i.e., the regression coefficient on the *AQ Factor* beta) is significant after controlling for the three Fama-French factor loadings when cash flow shocks are excluded using nonlinear cross-sectional or firm-specific time-series return decomposition methods. The statistically significant *AQ Factor* premium estimates range from 3.6 percent to 4.68 percent on the annualized basis.

In summary, I provide evidence suggesting that accrual quality, as measured using the Dechow-Dichev model, is associated with future realized returns after controlling for cash flow shocks. However, the results should be interpreted with caution because they are sensitive to the return decomposition method.

I perform two additional analyses aimed at strengthening the conclusions of the paper. First, I directly estimate unconditional expected returns for each firm from the firm-specific time-series returns-earnings surprise regressions. When the resulting expected returns are used in asset-pricing tests in place of returns excluding cash flow shocks, the premiums on accrual quality remain statistically and economically significant in all characteristic- and factor-loading-based tests. Second, I address the proposed return decomposition's inability to capture the discount rate shocks, i.e., the portion of returns due to changes in the expectation of future discount rates. If such shocks are negatively related to accrual quality, then they represent a correlated omitted variable that biases asset-pricing tests toward finding an accrual quality premium. However, additional tests show that the correlation between accrual quality and proxies for future discount rate shocks is positive, suggesting that discount rate shocks are unlikely to be responsible for the positive and significant premiums on accrual quality.

---

[5] This sample has five additional recent years not included in the CGV and FLOS (2005) samples. Including more years following the recent accounting scandals (e.g., Enron) should lend more power to tests that explore the asset-pricing implications of accounting quality.

[6] The look-ahead bias stems from using one-year-ahead cash flow to construct *DD Measure*. The tests are robust to using a non-lagged *DD Measure*, as discussed in Section V.

This paper contributes to the literature in two ways. First, it sheds light on the recent debate as to whether realized returns reflect the risk premium associated with poor accrual quality (FLOS 2005; CGV 2007). Second, it underscores the importance of controlling for cash flow shocks in asset-pricing tests that use realized returns to proxy for cost of equity, and develops a simple methodology that excludes cash flow shocks from the realized returns.

The conclusions of the paper are subject to the following caveats. First, the proposed return decomposition methodology assumes non-stochastic discount rates and relies solely on earnings surprises to capture news about future payoffs to shareholders. Second, the empirical tests in the paper seek to provide evidence on the existence of a premium related to accrual quality. The paper does not suggest a complete multi-factor asset-pricing model that fully explains the cross-section of expected returns. Such an objective would require asset-pricing tests to satisfy additional restrictions (Lewellen et al. 2010).

The rest of the paper proceeds as follows. Section II reviews the related literature, develops the paper's hypotheses, and describes the methodology used to control for cash flow shocks. Section III describes the sample selection procedures and the data. Section IV describes the main empirical analyses and results, Section V reports additional analyses and robustness checks, Section VI discusses methodology limitations, and Section VII presents my conclusions.

II. MOTIVATION

Prior Literature

Analytical Literature

The theoretical foundation for the link between accrual quality and the cost of equity comes from analytical models in the estimation risk and market microstructure literatures.[7] The estimation risk literature (e.g., Klein and Bawa 1976; Barry and Brown 1985; Coles et al. 1995) suggests that securities with less information about past return realizations should earn higher expected returns. Further, Lambert et al. (2007, 2009) suggest that firms with more precise information about future cash flows have lower conditional covariances with the market and, as a consequence, lower conditional betas and lower expected returns. The estimation risk literature suggests the following two-step link: (1) firms with higher information quality have lower forward-looking betas; and (2) lower forward-looking betas lead to lower cost of equity. Note that the traditionally estimated CAPM betas assume no differences in estimation risk across securities and therefore are an imperfect proxy for forward-looking betas.

The market microstructure literature (Amihud and Mendelson 1986) argues that a stock's expected return increases with the magnitude of the bid-ask spread to compensate for higher transaction costs. Higher information quality may decrease the firm's cost of equity by lowering the adverse selection component of the bid-ask spread.[8]

---

[7] In this section, I discuss only models that relate the quality of information to the cost of equity under conditions that are directly applicable to asset-pricing tests in the presence of diversification opportunities with multiple firms and multiple traders in the market. A number of models explore the effects of information asymmetry on liquidity but do not have clear implications for expected returns and are directly applicable only to the setting of equity issues, such as IPOs and SEOs, e.g., Diamond and Verrecchia (1991).

[8] In addition, Easley and O'Hara (2004) model the effect of information asymmetry on the cost of equity. In their model, poorly informed investors demand compensation for their informational disadvantage *vis-à-vis* more informed investors. However, two recent papers dispute the conclusions of Easley and O'Hara (2004). Hughes et al. (2007) argue that after controlling for factor betas, there is no cross-sectional relation between expected returns and the degree of information asymmetry, although information asymmetry affects factor premiums. Lambert et al. (2009) show that after controlling for the average precision of information, the degree of information asymmetry is not related to expected returns.

Overall, while analytical models suggest different mechanisms through which information quality affects cost of equity, they imply similar empirical predictions regarding the association between accrual quality and cost of equity. If low accrual quality increases estimation risk or information asymmetry, then low accrual quality stocks should earn higher returns.

The above two streams of research can also be used to derive a risk factor related to accrual quality. For example, Kogan and Wang (2003) show that a model with estimation risk or parameter uncertainty can be recast in a multi-factor asset-pricing framework with a separate factor related to estimation risk, while Easley et al. (2010) argue that there is a separate risk factor related to information asymmetry.

Empirical Literature

Most empirical studies use the Dechow and Dichev (2002) measure of residual accrual volatility (*DD Measure*) to infer the association between accrual quality and cost of equity.[9] The *DD Measure* is estimated as the standard deviation of residuals from a regression of working capital accruals on past, current, and future operating cash flows. Higher *DD Measures* indicate lower accrual quality.

Several studies document a higher cost of equity for firms with low accrual quality (high *DD Measures*) using alternative cost of equity measures, including (1) implied cost of equity (FLOS 2004; CGV 2007); (2) CAPM betas (FLOS 2004; Liu and Wysocki 2007); and (3) industry-adjusted earnings-to-price ratios (FLOS 2004; Liu and Wysocki 2007).[10]

In contrast, the evidence concerning the relation between cost of equity and accrual quality based on realized stock returns is mixed. FLOS (2004, 2005) form a factor-mimicking portfolio *AQ Factor* based on *DD Measure* and document that the return on *AQ Factor* is positively correlated with realized returns on individual stocks. Nichols (2006) documents significant abnormal daily returns on *AQ Factor*. In contrast, Aboody et al. (2005) find that the hedge return earned by taking a long (short) position in the stocks with high (low) *AQ Factor* loadings is not statistically significant. Further, CGV point out that while FLOS (2004, 2005) show that the average loading on *AQ Factor* is positive, to conclude that *AQ Factor* is a priced risk factor also requires establishing that stocks with higher loadings on *AQ Factor* have higher average realized returns. CGV perform standard two-stage asset-pricing tests (Fama and MacBeth 1973) and find that the loadings on *AQ Factor* do not explain the cross-sectional variation in returns. The premium on the *AQ Factor* is neither economically nor statistically significant. They also document that the *DD Measure* characteristic does not predict future monthly realized returns. CGV thus conclude that the significant returns on *AQ Factor* found by Nichols (2006) result from the daily portfolio re-balancing implicitly imposed by using equally weighted daily portfolio returns.

Resolving the debate on the existence of a priced risk factor related to accrual quality is important because a large number of studies implicitly or explicitly rely on its existence, including the following studies that use the loadings on *AQ Factor* to proxy for accounting quality: Ecker et al. (2006), Chen et al. (2007), Kravet and Shevlin (2010), Krishnan et al. (2008), Kim and Venkatachalam (2011), Ecker (2009), Bhattacharya et al. (2009), and Chang et al. (2009).

---

[9] Empirically, the association between accounting quality and the cost of equity has been tested using a variety of definitions for accounting quality, including the overall quality of disclosures (e.g., Botosan 1997; Botosan and Plumlee 2002; Berger et al. 2006) and the quality of specific accounting metrics such as earnings (e.g., Barth et al. 2011; Bhattacharya et al. 2003). These studies generally find that firms with low-quality accounting information are penalized with a higher cost of equity. For the sake of brevity, I only review studies using accrual quality, and *DD Measure* in particular, to proxy for the quality of accounting information.

[10] However, Liu and Wysocki (2007) argue that any asset-pricing effects of *DD Measure* are attributable to the underlying operating risk captured by cash flow variability and idiosyncratic return volatility.

To summarize, while analytical models suggest a negative link between information quality and firms' cost of equity, empirical research relating accrual quality, measured using *DD Measure*, to cost of equity (expected returns) provides mixed evidence. Importantly, standard asset-pricing tests provide little evidence that the stock market prices accrual quality risk associated with *DD Measure*.

The *DD Measure* and Cash Flow Shocks

Standard asset-pricing tests use average realized stock returns to capture the cost of equity. However, realized returns measure cost of equity with error due to information shocks (e.g., Elton 1999). Realized returns include three components: the expected return, the return due to cash flow news, and the return due to discount rate news (Campbell 1991). Of these three components, only the expected return reflects the firm's cost of equity. Conventional asset-pricing tests that use average realized stock returns to proxy for expected returns implicitly assume that realized stock returns on average are equal to expected returns. This assumption need not hold *ex post* in finite data samples. For example, Elton (1999) finds that historical realized returns deviate from expected returns for extended periods of time.[11] If firms with lower (higher) levels of accrual quality systematically received more (less) negative cash flow news during the sample period, then asset-pricing tests that use average realized returns as a proxy for expected returns are biased against finding a positive relationship between accrual quality and the cost of equity. Such bias is present in the risk premium estimates generated by all types of cross-sectional asset-pricing tests, independent of whether the analysis is at the stock or portfolio level or whether the basis of testing is characteristics or factor loadings. The magnitude of the bias is proportional to the correlation between accrual quality and future cash flow shocks.[12] A sufficiently large negative correlation may produce insignificant risk premium estimates.

The evidence in prior empirical research is indirectly consistent with firms with higher *DD Measure* (lower accrual quality) experiencing more negative cash flow shocks in the near future. Several characteristics that are correlated with *DD Measure* are also related to future abnormal stock returns, possibly due to cash flow shocks. For example, Dechow and Dichev (2002) document that firms with higher *DD Measure* have a higher frequency of losses, which is consistent with financial distress. Distressed firms earn significantly lower returns compared to the rest of the stock market (Dichev 1998), possibly due to systematic future negative cash flow shocks.

Firms with higher *DD Measure* also have more variable earnings and sales (Dechow and Dichev 2002). Mohanram (2005) shows that growth firms (with low book-to-market ratios) with more variable earnings or sales growth earn significantly lower future returns compared to their industry peers. He explains this effect by a naïve extrapolation of good past earnings or sales performance that is likely to be less sustainable for highly variable earnings or sales. In a similar vein, *DD Measure* is positively related to past sales growth (Doyle et al. 2007). Lakonishok et al. (1994) document that stocks with higher past sales growth earn negative abnormal returns, which possibly results from the market correcting initial overpricing of these stocks.

Finally, through its correlation with losses, *DD Measure* may be directly related to the fundamental signals that predict future returns. Piotroski (2000) demonstrates that the stock market does not fully appreciate the implications of fundamental signals related to the financial health of the firm for the firm's future performance.

---

[11] Fama and French (2002) also provide evidence supportive of persistent deviations of average realized returns calculated *ex post* from expected returns. They write that "the high average return for 1951 to 2000 is due to a decline in discount rates that produces a large unexpected capital gain . . . The average stock return of the last half century is a lot higher than expected" (Fama and French 2002, Abstract).

[12] I use the terms "cash flow news" and "cash flow shocks" interchangeably.

Overall, prior literature identifies several characteristics that predict future abnormal returns and are associated with *DD Measure*. To the extent that the documented abnormal returns are related to cash flow shocks, the average realized returns on the stocks with high *DD Measure* and low accrual quality (low *DD Measure* and high accrual quality) reflect on average adverse (positive) cash flow news and produce a downwardly (upwardly) biased estimate of the cost of equity. The asset-pricing tests that use average realized returns are therefore biased against finding a positive risk premium related to accrual quality.

Controlling for Cash Flow Shocks

To purge realized stock returns of cash flow shocks, I rely on the framework from accounting literature on earnings response coefficients (ERCs).[13] A cash flow shock is a stock price reaction due to a revision in the expectation of the entire stream of future cash flows. Since over the life of the firm the sum of cash flows should be equal to the sum of earnings, a cash flow shock can be measured as the return associated with an earnings surprise. For example, Kormendi and Lipe (1987) express the total realized return on stock i as the sum of three components: the expected return, the return due to a revision in the expectation of future earnings (i.e., cash flow shock), and the unexpected return unrelated to the earnings surprise:

$$r_{it+1} = E(r_{it+1}) + r^{CF}_{i,t+1} + \varepsilon^{*}_{i,t+1}, \qquad r^{CF}_{i,t+1} = \sum_{s=0}^{\infty} \beta^{s} \frac{\Delta E(X_{t+1+s}|UX_{t+1})}{P_t}, \tag{1}$$

where $E(r_{it+1})$ is the expected return for t+1; $r^{CF}_{i,t+1}$ is the cash flow shock portion of the return for period t+1; $\varepsilon^{*}_{i,t+1}$ is the unexpected return unrelated to the earnings surprise; X_{t+1} is earnings; UX_{t+1} is the earnings surprise; $\Delta E(X_{t+1+s}|UX_{t+1})$ is the revision in the expectation of earnings for t+1+s occurring between periods t and t+1 as a result of observing the earnings surprise, and β is a discount factor equal to $1/(1+r)$.[14]

Collins and Kothari (1989) show that, under various assumptions regarding the time series process of earnings, the cash flow shock can be expressed as a function of only the current-period earnings surprise:

$$r^{CF}_{i,t+1} = \phi \frac{UX_{t+1}}{P_t}, \tag{2}$$

where ϕ is an ERC that is positively related to earnings surprise persistence and negatively related to the discount rate.

Substituting Equation (2) into Equation (1) produces a return decomposition that is implied by the ERC framework:

$$r_{it+1} = E(r_{it+1}) + \phi \frac{UX_{t+1}}{P_t} + \varepsilon^{*}_{i,t+1}, \qquad r^{CF}_{i,t+1} = \phi \frac{UX_{t+1}}{P_t}. \tag{3}$$

---

[13] The literature includes several alternative ways of decomposing unexpected returns into cash flow shock and non-cash flow shock components. For example, Campbell (1991), Vuolteenaho (2002), Larocque (2009), and Callen and Segal (2004) decompose realized returns into cash flow shocks and discount rate shocks using a vector autoregression approach, and Campello et al. (2008) use bond returns to back out expected stock returns. While comparisons between these approaches is outside the scope of this paper, each approach has its own merits and limitations. Campello et al.'s (2008) method requires that all firms have outstanding public debt, which drastically reduces the available sample size. The disadvantages of the Campbell (1991) approach are discussed in detail in Chen and Zhao (2009), and their research design is, in turn, critiqued in Engsted et al. (2010).

[14] The decomposition assumes that the discount rate r is constant over time. To the extent that r is not constant, the realized returns also contain discount rate shocks. In Section V, I discuss the potential implications of non-constant discount rates in the accrual quality setting.

From Equation (3), the cash flow shock portion of the return, $r_{i,t+1}^{CF}$, can be estimated as the fitted value from the cross-sectional regression of realized returns on earnings surprises $UX_{i,t+1}$.[15] Accordingly, I perform a two-step estimation of $r_{i,t+1}^{CF}$. First, I estimate earnings surprises (*SURP*) based on the expectation of earnings derived from a simple statistical earnings prediction model that assumes that annual earnings follow an AR(1) process. I estimate this model cross-sectionally for the hold-out period of one year by regressing current-year earnings on the previous year's earnings. I use the resulting coefficients to construct the next year's predicted earnings. Appendix A provides details on the estimation of earnings surprises.

Second, I estimate the cash flow shock portion of the realized return using cross-sectional or time-series return decomposition. The cross-sectional decomposition involves running monthly cross-sectional regressions of excess stock returns on contemporaneous earnings surprises. The fitted values from these regressions represent cash flow shock returns ($r_{i,t+1}^{CF}$), while the residuals plus the intercept represent returns excluding cash flow shocks, which I call non-cash flow shock returns ($r_{i,t+1}^{NCF}$). Because this estimation assumes a linear relation between earnings surprises and realized returns, I refer to it as the *linear earnings response model*.

The above estimation assumes that the magnitude of ERCs is constant across all firms in the cross-section. However, the literature on the determinants of ERCs suggests that the return response is lower for extreme and/or negative earnings surprises (e.g., Freeman and Tse 1992; Cheng et al. 1992). To account for the resulting nonlinearity in the returns-earnings relation, I estimate cross-sectional regressions of excess stock returns on earnings surprise variables within 5 percent intervals over the earnings surprise distribution. This *nonlinear earnings response model* allows ERCs to vary depending on the magnitude of earnings surprises and produces more accurate cash flow shock estimates.

The time-series return decomposition involves estimating firm-specific regressions of excess returns on earnings surprises using at least 72 monthly returns over at least six fiscal years. Prior research (Lipe et al. 1998) shows that letting ERCs vary by firm explains significantly more variation in returns compared to nonlinear cross-sectional returns-earnings surprise regressions. This estimation, which I call the *firm-specific earnings response model*, estimates cash flow news more precisely. Throughout the paper I report the results obtained using all three decompositions, but I emphasize the results obtained using the more accurate firm-specific decomposition.

III. SAMPLE AND DATA

The sample consists of 92,145 firm-years with fiscal years from 1970 to 2006 and with returns available from April 1971 to March 2008.[16,17] Some tests require additional data causing further sample restrictions.

The *DD Measure* is estimated similarly to FLOS (2005). First, the following cross-sectional regression is estimated for each year and each of the 48 Fama and French (1997) industries (at least

---

[15] Other studies that use earnings and earnings forecasts to proxy for cash flow news include Barth et al. (2008) and Campbell et al. (2010). Barth et al. (2008) use analysts' forecast revisions to measure cash flow news in the context of credit risk evaluation. Campbell et al. (2010) use changes in discounted sums of ROE to proxy for the cash flow shock portion of realized stock returns.

[16] The sample consists of observations with necessary data to calculate the *DD Measure*, the market value of equity, book-to-market, and CAPM beta. In addition, observations should have at least one month with a non-missing return in CRSP within the estimation period (the 12 months starting with the fourth month after the fiscal year-end).

[17] To avoid spuriously inflating the returns to the trading strategies based on accrual-related variables (Beaver et al. 2007), all asset-pricing tests incorporate delisting returns for the firms that delist from the exchanges within the estimation period. If the delisting return is missing in CRSP, I replace it with the average delisting return from Shumway (1997) and Shumway and Warther (1999).

20 observations are required for each regression):

$$TCA_{it} = \alpha_t + \beta_{1t}CFO_{it-1} + \beta_{2t}CFO_{it} + \beta_{3t}CFO_{it+1} + \beta_{4t}\Delta REV_{it} + \beta_{5t}PPE_{it} + \varepsilon_{it}, \tag{4}$$

where:

TCA_{it} = total current accruals for year t estimated using the balance sheet approach:
$TCA_{it} = \Delta CA_{it} - \Delta CL_{it} - \Delta Cash_{it} + \Delta STDEBT_{it}$,

where ΔCA_{it} is one-year change in current assets (Compustat #4); ΔCL_{it} is one-year change in current liabilities (Compustat #5); $\Delta Cash_{it}$ is one-year change in cash (Compustat #1); and $\Delta STDEBT_{it}$ is one-year change in current liabilities (Compustat #34);

CFO_{it} = cash flow from operations for year t estimated as $NIBE_{it} - TA_{it}$, where $NIBE_{it}$ is net income before extraordinary items (Compustat #18); and TA_{it} is total accruals ($TA_{it} = TCA_{it} - DEPN_{it}$ where $DEPN_{it}$ is depreciation and amortization expense in year t (Compustat #14));
ΔREV_{it} = one-year change in revenues (Compustat #12); and
PPE_{it} = property, plant, and equipment for year t (Compustat #7).

Subscript i refers to individual firms. All variables are scaled by the average value of total assets (Compustat #6) over years t–1 and t.

DD Measure for each firm i and each year t is the standard deviation of the residuals from the above cross-sectional regression over the period [t–5, t–1]. To prevent the look-ahead bias, the estimation period is lagged by one year compared to the period used in FLOS (2005).[18] *DD Measure* is converted to decile ranks in all asset-pricing tests. The sorting into deciles is performed monthly and each stock is assigned a rank based on the *DD Measure* from the most recent fiscal year that ends 16 to 4 months prior to the sorting. For example, the ranking for July 2004 is based on the *DD Measure* from the latest fiscal year that ended between April 2003 and March 2004.

IV. EMPIRICAL ANALYSES AND RESULTS

Replicating CGV using the *DD Measure* and Future Stock Returns

Accrual Quality Characteristic and Future Returns

CGV document that neither the accrual quality characteristic (*DD Measure*) nor the exposure to accrual quality risk (the loading on *AQ Factor*) can predict future stock returns. I replicate CGV's results for an extended sample period that includes five additional fiscal years from 2002 to 2006.

Panel A of Table 1 replicates the characteristic-based analysis of CGV. The following cross-sectional regression is estimated monthly using individual stock returns (the i subscript refers to individual stocks):

$$R_{i,t+1} - R^f_{t+1} = \text{Intercept}_t + q_t RDD_{it} + b_t BETA_{it} + s_t MKTV_{it} + h_t BMRATIO_{it} + \varepsilon_{it}, \tag{5}$$

where:

R_{it+1} = return on stock i for month t+1;

---

[18] The tests are robust to using non-lagged *DD Measure*, as discussed in Section V.

TABLE 1

(continued on next page)

TABLE 1 (continued)

The table presents results of asset-pricing tests for a sample of 92,145 firm-year observations with fiscal years ending in 1970 to 2006 and monthly returns collected from April 1971 to March 2008. All returns are reported in percentages.
Panel A reports mean coefficient estimates from the cross-sectional regression:

$$R_{i,t+1} - R^f_{t+1} = \text{Intercept}_t + q_t RDD_{it} + b_t BETA_{it} + s_t MKTV_{it} + h_t BMRATIO_{it} + \varepsilon_{it},$$

where $R_{i,t+1} - R^f_{t+1}$ denotes the realized return in excess of the one-month T-bill rate for stock *i* and month *t*+1; RDD_{it} is the decile rank based on *DD Measure*; $BETA_{it}$ is the CAPM beta estimated using five years of data ending the most recent December; $MKTV_{it}$ is the natural logarithm of the market value of equity; and $BMRATIO_{it}$ is the natural logarithm of the ratio of book value of equity to market value of equity, where book value is stockholders' book equity plus deferred taxes minus the book value of preferred stock, and the market value of equity is as previously defined. *DD Measure*, $MKTV_{it}$, and $BMRATIO_{it}$ are estimated for the most recent fiscal year ending at least three months prior to month *t*. Reported coefficients and adjusted R^2s are the average values from 444 monthly cross-sectional regressions. Two-sided Fama-MacBeth p-values are reported in parentheses.
Panel B reports descriptive statistics for the returns on *AQ Factor* and the three Fama-French factors. R^{MktRf} is the excess return on the market portfolio. R^{SMB} is the return on the size factor-mimicking portfolio. R^{HML} is the return on the book-to-market factor-mimicking portfolio. The R^{AQ} is an equal-weighted return on a hedge portfolio that is long (short) in the two top (bottom) quintiles of *DD Measure*.
Panel C reports coefficient estimates for the regression:

$$R^{AQ}_t = \alpha + \beta R^{MktRf}_t + s R^{SMB}_t + h R^{HML}_t + \varepsilon_t,$$

where $R^{AQ}{}_t$ is the return on *AQ Factor* for month *t* and all other variables are as defined above. The regression is based on a series of 444 monthly returns. Two-sided p-values are reported in parentheses.
Panel D reports regression coefficients for the portfolio-level cross-sectional regressions based on the full-period average excess returns and the full-period factor betas:

$$\bar{R}_i - \bar{R}^f = \text{Intercept} + \hat{b}_i^{AQ}\lambda^{AQ} + \hat{b}_i^{MktRf}\lambda^{MktRf} + \hat{b}_i^{SMB}\lambda^{SMB} + \hat{b}_i^{HML}\lambda^{HML} + \varepsilon_{it},$$

where $\bar{R}_i - \bar{R}^f$ is the average excess return on portfolio *i* calculated using 444 monthly portfolio returns, and $\hat{b}_i^{AQ}, \hat{b}_i^{MktRf}, \hat{b}_i^{SMB}$, and $\hat{b}_i^{HML}$ are full-period factor betas estimated from the regression:

$$R_{it} - R^f_t = \alpha_i + b_i^{AQ}R_t^{AQ} + b_i^{MktRf}R_t^{MktRf} + b_i^{SMB}R_t^{SMB} + b_i^{HML}R_t^{HML} + \varepsilon_{it},$$

where R_{it} is the equal-weighted return on portfolio *i* for month *t* and all other variables are as defined above. Each regression is based on a series of 444 monthly returns. Two-sided Fama-MacBeth p-values adjusted for the Shanken (1992) correction (reported in parentheses) are based on the coefficients obtained by estimating the cross-sectional regression monthly. The panel partitions refer to three types of portfolios: (1) "25 B/M and Size Portfolios" are based on quintiles of the book-to-market ratio and size; (2) "100 *DD Measure* Portfolios" are based on percentiles of *DD Measure*; and (3) "64 B/M, Size, and *DD Measure* Portfolios" are based on quartiles of the book-to-market ratio, size, and *DD Measure*.
For each firm and each year *t*, *DD Measure* is calculated as the standard deviation of residuals over the [*t*–5, *t*–1] period, where residuals are obtained from the following regression estimated cross-sectionally for each year, and each of the 48 Fama and French (1997) industries:

$$TCA_{it} = \alpha_t + \beta_{1t}CFO_{it-1} + \beta_{2t}CFO_{it} + \beta_{3t}CFO_{it+1} + \beta_{4t}\Delta REV_{it} + \beta_{5t}PPE_{it} + \varepsilon_{it},$$

where TCA_{it} is total current accruals for year *t* (estimated using the balance sheet approach: $TCA_{it} = \Delta CA_{it} - \Delta CL_{it} - \Delta Cash_{it} + \Delta STDEBT_{it}$, where ΔCA_{it} is one-year change in current assets (#4); ΔCL_{it} is one-year change in current liabilities (#5); $\Delta Cash_{it}$ is one-year change in cash (#1); $\Delta STDEBT_{it}$ is one-year change in debt in current liabilities (#34)); CFO_{it} is cash flow from operations for year *t* estimated as $NIBE_{it} - TA_{it}$, where $NIBE_{it}$ is net income before extraordinary items (#18); TA_{it} is total accruals ($TA_{it} = TCA_{it} - DEPN_{it}$, where $DEPN_{it}$ is depreciation and amortization expense in year *t* (#14)); ΔREV_{it} is one-year change in revenues (#12); PPE_{it} is property, plant, and equipment for year *t* (#7). All variables are scaled by the average value of total assets (Compustat #6) over years *t*–1 and *t*. At least 20 observations are required for each regression. All numbered items in the description of variables refer to Compustat annual data items.

R^f_{t+1} = one-month T-bill rate for month $t+1$;

RDD_{it} = decile rank based on the *DD Measure* determined at the end of month t as described in Section III;

$BETA_{it}$ = CAPM beta estimated using 60 months of data prior to the most recent January;

$MKTV_{it}$ = natural logarithm of market value of equity at the latest fiscal year-end preceding month t by at least three months; and

$BMRATIO_{it}$ = natural logarithm of the book-to-market ratio at the latest fiscal year preceding month t by at least three months where book value is stockholders' book equity plus deferred taxes minus the book value of preferred stock and market value of equity is as defined previously.

The mean coefficient estimates are based on monthly estimates from the cross-sectional regressions. The p-values are based on Fama-MacBeth (1973) t-statistics that rely on the time-series distribution of cross-sectional coefficients. The coefficient on the rank of *DD Measure* (*RDD*) represents the increase in the average realized return from one decile of *DD Measure* to the next; when multiplied by 9, it can be converted to the difference in average returns between the first and tenth deciles of *DD Measure*.

The results in Panel A of Table 1 are similar to those reported in CGV. Specifically, the coefficient on *RDD* is positive but not significant for the regression without controls, and is negative and not significant when the CAPM beta, market value of equity, and book-to-market ratio are added as controls.

The above results are based on the cross-section of individual stock returns. Next, I verify that *DD Measure* does not predict future returns at the portfolio level. As in FLOS and CGV, I form a factor-mimicking portfolio (*Accrual Quality* [*AQ*] *Factor*) by taking a short (long) position in the stocks falling in the two bottom (top) quintiles of *DD Measure* at the beginning of each month.

Panel B of Table 1 reports the descriptive statistics for *AQ Factor* and for the three Fama and French (1993) factors—market premium (*MktRf*), size (*SMB*), and book-to-market (*HML*). The raw return on *AQ Factor* (0.08 percent per month) is not statistically significant.

Panel C of Table 1 presents the results of regressing *AQ Factor* returns on the three Fama-French factor returns. Collectively, the Fama-French factors explain 55 percent of the variation in *AQ Factor* and there is no evidence of an abnormal return earned on *AQ Factor*. The intercept of the regression, Jensen's alpha, is equal to 0.02 percent per month and is not statistically significant. Overall, there is no evidence that lower accrual quality, as proxied by *DD Measure*, is associated with higher stock returns, consistent with CGV's result.

AQ Factor Loadings and Future Stock Returns

Although thus far I find no evidence that *DD Measure* predicts future returns, it is possible that *DD Measure* is a noisy proxy for the systematic component of accrual risk, i.e., the returns' co-variation with *AQ Factor*. To establish whether the co-variation with *AQ Factor* is priced by the market, I perform a two-stage analysis that is similar to that reported in CGV.

The two-stage technique is used extensively in the asset-pricing literature to verify whether the loadings on the candidate factor explain the cross-sectional variation in expected stock returns, i.e., whether stocks with higher "betas" earn higher returns on average (e.g., Fama and MacBeth 1973; Jagannathan and Wang 1996). The first stage involves estimating loadings on a set of factors—"factor betas"—by regressing returns for each portfolio on the contemporaneous factor returns. The first-stage regressions use the entire time-series of returns and are estimated separately for each portfolio, where subscripts i and t refer to portfolios and months, respectively:

$$R_{it} - R_t^f = \alpha_i + b_i^{AQ} R_t^{AQ} + b_i^{MktRf} R_t^{MktRf} + b_i^{SMB} R_t^{SMB} + b_i^{HML} R_t^{HML} + \varepsilon_{it}, \tag{6}$$

where:

R_{it} = return on portfolio i for month t;
R_t^f = one-month T-bill rate;
R_t^{AQ} = return on *AQ Factor*;
R_t^{MktRf} = return on a market portfolio (CRSP value-weighted index) in excess of the risk-free rate;
R_t^{SMB} = return on a factor-mimicking hedge portfolio for size; and
R_t^{HML} = return on a factor-mimicking hedge portfolio for book-to-market.

The second stage involves a cross-sectional regression of realized returns on the factor loadings estimated in the first stage:

$$\bar{R}_{it} - R_{it}^f = \text{Intercept}_t + \hat{b}_i^{AQ} \lambda_t^{AQ} + \hat{b}_i^{MktRf} \lambda_t^{MktRf} + \hat{b}_i^{SMB} \lambda_t^{SMB} + \hat{b}_i^{HML} \lambda_t^{HML} + \varepsilon_{it}, \tag{7}$$

where:

$\bar{R}_{it}$ = average return on portfolio i for month t;
R_{it}^f = one-month T-bill rate for month t; and
$\hat{b}_i^{AQ}$, $\hat{b}_i^{MktRf}$, $\hat{b}_i^{SMB}$, $\hat{b}_i^{HML}$ = factor betas estimated in the first stage.[19]

The premium magnitudes are estimated from a single cross-sectional regression (7), using averages of monthly portfolio returns. The statistical significance of the regression coefficients is derived from estimating regression (7) monthly and computing Fama-MacBeth (1973) t-statistics adjusted for the Shanken (1992) correction.

Panel D of Table 1 reports the results of a second-stage estimation for three sets of portfolios: (1) 25 portfolios formed by independently sorting stocks into quintiles based on book-to-market and size; (2) 100 portfolios based on the percentiles of *DD Measure*; and (3) 64 portfolios formed by independently sorting stocks into quartiles based on book-to-market, size, and *DD Measure*. Portfolio returns are calculated by equal-weighting the individual stock returns.[20] For each portfolio set, I estimate three types of factor models: (1) the benchmark model that includes only the three Fama-French (1993) factors; (2) the benchmark model that includes only *AQ Factor*; and (3) the full model, which includes the three Fama-French factors plus *AQ Factor*. The results are consistent with the findings in CGV—the *AQ Factor* premium, i.e., the regression coefficient on b_i^{AQ}, is not statistically significant for any model specification.

Overall, CGV's results are confirmed for my sample period. Higher exposure to accrual quality risk, as proxied by the loading on *AQ Factor*, is not associated with higher stock returns.

The *DD Measure* and Future Stock Returns: Controlling for Cash Flow Shocks

The analyses presented in this section are constrained by the availability of data required for return decomposition. The cross-sectional (time-series) return decomposition requires non-missing earnings surprises (and at least 72 months with non-missing returns and earnings surprises per firm), which constrains the sample to 86,553 (75,026) observations.

---

[19] When the second-stage regressions include only a subset of estimated loadings, i.e., only $\hat{b}_i^{AQ}$, the factor betas are based on the first-stage regressions that include only the corresponding subset of factor returns, i.e., only the return on *AQ Factor*.

[20] The weighting procedure is different from that in CGV, who use value-weighting to calculate portfolio returns. While value-weighting has been used frequently in prior literature (e.g., Fama and French 1993), equal-weighting is also acceptable (e.g., Carhart 1997). To detect the effect of accrual quality, it may be preferable to use equal-weighting since it is likely that the quality of accruals, and accounting information in general, is more important for smaller firms with less saturated information environments.

Descriptive Statistics

Panels A and C of Table 2 report descriptive statistics for excess returns and its two components, cash flow shocks ($r_{i,t+1}^{CF}$) and returns excluding cash flow shocks ($r_{i,t+1}^{NCF}$). On average, cash flow shocks are either slightly negative or positive (positive) using linear or nonlinear return decomposition in Panel A (firm-specific decomposition in Panel C). As a result, returns excluding cash flow shocks are on average equal to or lower than the realized excess returns, and are negative in over 50 percent of observations across all decomposition methods. Note however that returns excluding cash flow shocks are not equal to expected returns, i.e., cost of capital. First, they represent returns in excess of risk-free rates because the decomposition is based on excess returns. Second, and more importantly, they contain discount rate shocks, which can *ex post* be negative in a given month, or even on average for a finite sample period. To the extent that discount rate shocks are not positively correlated with *DD Measure*, this shock contamination introduces noise in the analyses but does not cause spurious results. Empirical evidence presented in Section V is consistent with the absence of such positive correlation.

Univariate Analysis

In Section II, I conjecture that stocks with higher *DD Measure* (lower accrual quality) experienced more negative cash flow shocks in my sample period. To test this conjecture, I first verify that poor accrual quality stocks experienced on average more negative earnings surprises.

Panels B and D of Table 2 report mean earnings surprise proxies by *DD Measure* decile for the cross-sectional and time-series return decomposition samples. There is a strong negative monotonic relation between *DD Measure* and earnings surprises. The average differences in earnings surprises between the worst (Decile 10) and the best (Decile 1) accrual quality stocks, reported in the row "10 – 1," are negative and statistically significant (p-value 0.00).

Next, I examine whether the significantly more negative earnings surprises experienced by poor accrual quality stocks translate into significantly lower cash flow shocks. Panels B and D of Table 2 report the mean total realized excess returns decomposed into cash flow shock ($r_{i,t+1}^{CF}$) and non-cash flow shock ($r_{i,t+1}^{NCF}$) components by *DD Measure* decile. The decomposition in Panel B (Panel D) is based on the cross-sectional (time-series) estimation. The average differences in excess returns and return components between the worst (Decile 10) and the best (Decile 1) accrual quality stocks are reported in the row "10 – 1."

The second column of Panels B and D reports average excess returns by *DD Measure* decile. The differences between average returns of the extreme *DD Measure* deciles are not statistically significant, confirming CGV's result for the samples constrained by the return decomposition data requirements.

The remaining columns of Panel B (Panel D) report average cash flow shocks ($r_{i,t+1}^{CF}$) and returns excluding cash flow shocks ($r_{i,t+1}^{NCF}$) for the linear and nonlinear earnings response models (firm-specific earnings response model). Cash flow shocks are lower for stocks in the highest *DD Measure* decile across all earnings response models, with the magnitude of the "10 – 1" difference ranging from –0.25 percent to –0.35 percent monthly with p-values of at least 0.02.[21] In contrast, returns excluding cash flow shocks ($r_{i,t+1}^{NCF}$) are consistently higher for the worst (Decile 10) accrual quality stocks. The differences for returns excluding cash flow shocks reported in the row "10 – 1" range from 0.42 percent (p-value 0.19) to 0.68 percent (p-value 0.03).

---

[21] When discussing the statistical significance of risk premiums, I refer to coefficients with two-sided p-values of less than 0.10 as statistically significant because corresponding one-sided p-values testing directional hypothesis of positive risk premiums would be below 0.05.

p-value	(0.00)	(0.29)	(0.00)	(0.03)

The table reports descriptive statistics and compares earnings surprises, cash flow shocks, and realized returns excluding cash flow shocks from the cross-sectional (time-series) return decomposition across deciles of the accrual quality distribution for a sample of 86,553 (75,026) observations from 1970 to 2006.

Panel A (Panel C) contains descriptive statistics for returns decomposed using cross-sectional (time-series) regressions of excess returns on earnings surprises (*SURP*). The fitted values from these regressions represent cash flow shocks ($r^{CF}_{i,t+1}$), and the residuals plus intercepts represent returns excluding cash flow shocks ($r^{NCF}_{i,t+1}$). In Panel A, "Linear Earnings Response Model" refers to estimating ($r^{CF}_{i,t+1}$) and ($r^{NCF}_{i,t+1}$) from the monthly cross-sectional regressions for the full sample. The "Nonlinear Earnings Response Model" refers to estimating ($r^{CF}_{i,t+1}$) and ($r^{NCF}_{i,t+1}$) from the monthly cross-sectional regressions estimated separately within each of the 20 *SURP* portfolios. In Panel C, "Firm-Specific Earnings Response Model" refers to estimating ($r^{CF}_{i,t+1}$) and ($r^{NCF}_{i,t+1}$) from the firm-specific time-series regressions based on at least 72 monthly returns.

Panels B and D report means of earnings surprises (*SURP*), total excess returns, cash flow shocks ($r^{CF}_{i,t+1}$), and returns excluding cash flow shocks ($r^{NCF}_{i,t+1}$) by *DD Measure* decile. In Panel B (Panel D) returns are decomposed using cross-sectional (time-series) regressions of excess returns on earnings surprises (*SURP*). The average differences between earnings surprises and returns in the bottom and top deciles of accrual quality are reported in the row "10 − 1." The two-sided p-values for the return (earnings surprise) differences are computed using the Fama-MacBeth approach with a Newey and West (1987; hereafter, Newey-West) correction with six lags.

All returns are reported in percentages. Details of earnings surprise (*SURP*) estimation are in Appendix A.

Overall, the univariate results are consistent with firms with high *DD Measures* (low accrual quality) experiencing more negative cash flow shocks in my sample period. Firms with low accrual quality on average earned higher returns after excluding cash flow shocks, although the difference in returns between the extreme accrual quality deciles is statistically significant only for the time-series firm-specific result, the most powerful return decomposition.

AQ Characteristic and Future Stock Returns Excluding Cash Flow Shocks

Next, I examine whether *DD Measure* as a characteristic is significantly associated with realized returns after excluding cash flow shocks. Table 3 reports the stock-level regressions of future returns on the ranked *DD Measure* (*RDD*). The analyses reported in Panel A (Panel B) rely on the cross-sectional (time-series) return decomposition. The panels are further partitioned based

The table reports results of characteristic-based asset-pricing tests based on the realized returns after excluding cash flow shocks (r^{NCF}).

The sample in Panel A (Panel B) consists of 86,553 (75,026) observations over the 1970 to 2006 period and is restricted by the availability of an earnings surprise measure (*SURP*) (and at least 72 monthly returns for firm-specific return decomposition).

The table contains mean coefficient estimates from the cross-sectional regressions:

$$r^{NCF}_{i,t+1} = \text{Intercept}_t + q_t RDD_{it} + Controls + \varepsilon_{it},$$

where ($r^{NCF}_{i,t+1}$) denotes the realized return excluding cash flow shocks for stock *i* and month *t*+1; RDD_{it} is the decile rank based on *DD Measure*. All other variables are as defined in Table 1. The returns excluding cash flow shocks ($r^{NCF}_{i,t+1}$) are the residuals plus intercepts from the regressions of individual stock excess returns on earnings surprises. In Panel A, "Linear Earnings Response Model" refers to estimating ($r^{CF}_{i,t+1}$) and ($r^{NCF}_{i,t+1}$) from the monthly cross-sectional regressions for the full sample. The "Nonlinear Earnings Response Model" refers to estimating ($r^{CF}_{i,t+1}$) and ($r^{NCF}_{i,t+1}$) from the monthly cross-sectional regressions estimated separately within each of the 20 *SURP* portfolios. In Panel B, "Firm-Specific Earnings Response Model" refers to estimating ($r^{CF}_{i,t+1}$) and ($r^{NCF}_{i,t+1}$) from the firm-specific time-series regressions based on at least 72 monthly returns.

Reported coefficients and adjusted R^2s are the average values from 444 monthly cross-sectional regressions. Two-sided Fama-MacBeth p-values are reported in parentheses.

on the excess return measure used in the estimation. The first partition of each panel uses total excess returns; the remaining partitions use excess returns excluding cash flow shocks ($r^{NCF}_{i,t+1}$). The premiums on *RDD* using total excess returns are not statistically significant either before or after controlling for other risk-related characteristics (CAPM beta, market value of equity, and book-to-market), confirming that CGV's result holds for the constrained samples.

When excess returns excluding cash flow shocks are regressed on *RDD* without controlling for other risk-related characteristics, the premiums on *RDD* are consistently positive and significant at least at the 10 percent level across all return-decomposition methods in Panels A and B. The magnitude of the premium ranges from 0.04 percent to 0.06 percent monthly. The premium is also economically significant and can be interpreted as the difference between the highest and the lowest deciles of *DD Measure* of approximately 4.3 percent per annum (0.04 percent × 12 × 9) to 6.5 percent per annum (0.06 percent × 12 × 9).

The premium on *RDD* is reduced in magnitude after the CAPM beta (*BETA*), market value of equity (*MKTV*), and book-to-market ratio (*BMRATIO*) are included as additional controls.[22] The premium is no longer significant in Panel A where cash flow shocks are removed using cross-sectional return decomposition, but remains statistically significant in Panel B where cash flow shocks are removed using a more powerful firm-specific return decomposition. The premium reported in Panel B also remains economically significant—the difference in returns excluding cash flow shocks between the highest and the lowest deciles of accrual quality is approximately 3.24 percent per annum (0.03 percent × 12 × 9).[23]

In sum, accrual quality, as proxied by *DD Measure*, is significantly inversely related to future realized stock returns after controlling for cash flow shocks when the return decomposition relies on the most powerful—firm-specific time-series—model.

AQ Factor Loadings and Future Stock Returns Excluding Cash Flow Shocks

Table 4 contains the results of the second-stage regressions of realized returns on factor loadings. The analyses reported in Panel A (Panel B) rely on the sample available for the cross-sectional (time-series) return decomposition. The panels are partitioned by the types of portfolios and return measures used in the estimation.[24]

The first row of each partition in Panels A and B reports the results of the CGV replication for the constrained samples, where asset-pricing regressions are based on total excess returns. The premiums on *AQ Factor*, the coefficient on *AQ Factor* beta, are not significant in either constrained sample for any portfolio partition.

The second row of each partition in Panel A reports the results based on returns that exclude cash flow shocks using the linear earnings response model. The premium on *AQ Factor* is positive

---

[22] Untabulated results suggest that the premium reduction is driven by controlling for the market value of equity. When the market value of equity is decomposed into several components corresponding to market frictions, scale of operations, earnings announcement informativeness, and size risk, the premium on accrual quality is significantly reduced only by controlling for the market frictions component. It is therefore possible that the market value of equity captures higher information asymmetry or higher information risk exposure of low accrual quality stocks. A detailed path analysis of relationships between accrual quality and expected returns (e.g., Bhattacharya et al. 2012) is outside the scope of this paper.

[23] The 3.24 percent difference is substantial in terms of its effect on the market value of equity. For example, in the simple Gordon growth model, under a zero dividend growth assumption, price equals expected dividend divided by cost of capital. So, a 1 percent decrease in cost of capital approximately translates into a 1 percent increase in firm value. From Panel C of Table 2, the average annualized non-cash flow shock return for stocks within the worst accrual quality decile is 12.72 percent (1.06 percent × 12). The 3.24 percent decrease in expected return obtained by moving from the worst to the best accrual quality decile reduces cost of capital by 25 percent (3.24 percent/12.72 percent), with a corresponding 25 percent increase in the market value of equity.

[24] The *AQ Factor* loadings are based on *AQ Factor* returns adjusted for cash flow shocks.

The table reports results of the second stage of the two-stage asset-pricing tests based on the realized returns after excluding cash flow shocks (r^{NCF}). The sample in Panel A (Panel B) consists of 86,553 (75,026) observations over the 1970 to 2006 period and is restricted by the availability of an earnings surprise measure (*SURP*) (and at least 72 monthly returns for firm-specific return decomposition).

The table reports regression coefficients from the cross-sectional regressions based on the full-period average excess returns excluding cash flow shocks and the full-period factor betas:

$$\overline{r_i^{NCF}} = \text{Intercept} + \hat{b}_i^{AQ}\lambda^{AQ} + \hat{b}_i^{MktRf}\lambda^{MktRf} + \hat{b}_i^{SMB}\lambda^{SMB} + \hat{b}_i^{HML}\lambda^{HML} + \varepsilon_{it},$$

where $\overline{r_i^{NCF}}$ is the average excess return excluding cash flow shocks on portfolio *i* calculated using 444 monthly portfolio returns, and $\hat{b}_i^{AQ}$, $\hat{b}_i^{MktRf}$, $\hat{b}_i^{SMB}$, and $\hat{b}_i^{HML}$ are full-period factor betas estimated by regressing non-cash flow shock portfolio returns on factor returns.

The returns excluding cash flow shocks ($r_{i,t+1}^{NCF}$) are the residuals plus intercepts from the regressions of individual stock excess returns on earnings surprises. In Panel A, "Linear Earnings Response Model" refers to estimating ($r_{i,t+1}^{CF}$) and ($r_{i,t+1}^{NCF}$) from the monthly cross-sectional regressions for the full sample. The "Nonlinear Earnings Response Model" refers to estimating ($r_{i,t+1}^{CF}$) and ($r_{i,t+1}^{NCF}$) from the monthly cross-sectional regressions estimated separately within each of the 20 *SURP* portfolios. In Panel B, "Firm-Specific Earnings Response Model" refers to estimating ($r_{i,t+1}^{CF}$) and ($r_{i,t+1}^{NCF}$) from the firm-specific time-series regressions based on at least 72 monthly returns.

Each regression is based on a series of 444 monthly returns. Coefficients and adjusted R^2s are from a single cross-sectional regression that uses average portfolio returns. Two-sided Fama-MacBeth p-values adjusted for the Shanken (1992) correction (reported in parentheses) are based on the coefficients obtained by estimating the cross-sectional regression monthly. The panel partitions refer to three types of portfolios: (1) "25 B/M and Size Portfolios" are based on quintiles of the book-to-market ratio and size; (2) "100 *DD Measure* Portfolios" are based on percentiles of *DD Measure*; and (3) "64 B/M, Size, and *DD Measure* Portfolios" are based on quartiles of the book-to-market ratio, size, and *DD Measure*.

across all portfolios, but statistically significant at the 10 percent level only for the "100 *DD Measure*" portfolios that have the most power to detect the premium on accrual quality. The third row of each partition in Panel A reports the results based on the returns that exclude cash flow shocks using the nonlinear earnings response model. The premium on *AQ Factor* is between 0.30

percent and 0.37 percent monthly and is statistically significant across all portfolio partitions, with p-values ranging from 0.07 to 0.10. The premiums are also economically significant, ranging from 3.6 percent per annum (0.30 percent × 12) to 4.44 percent per annum (0.37 percent × 12).[25,26]

The second row of each partition in Panel B, Table 4 reports the results based on excluding cash flow shocks using the firm-specific earnings response model. The premium on *AQ Factor* is positive and statistically significant at the 10 percent level across all portfolio partitions, with the magnitudes of the premium ranging from 0.33 percent to 0.39 percent monthly. The corresponding annualized premiums range from 3.96 percent (0.33 percent × 12) to 4.68 percent (0.39 percent × 12).

Overall, the asset-pricing tests presented in this section provide evidence that is generally consistent with *AQ Factor* being priced in stock returns after controlling for the three Fama-French (1993) factors. The *AQ Factor* betas, i.e., the loadings on *AQ Factor*, are significantly positively related to future returns excluding cash flow shocks, when the latter are excluded using the two most powerful return decomposition models that take into account the nonlinearity in the returns-earnings surprise relation or allow earnings surprise coefficients to vary by firm.

V. ADDITIONAL ANALYSES AND ROBUSTNESS CHECKS

Alternative Return Decomposition

The methodology described in Section II decomposes returns in two parts: cash flow shocks (r^{CF}) and returns excluding cash flow shocks (r^{NCF}), with the latter being used in asset-pricing tests. In this section, I perform an alternative return decomposition based on the firm-specific earnings response model.

Equation (3) implies that intercepts from the firm-specific regressions of excess returns on earnings surprises can serve as proxies for unconditional time-invariant expected returns (r^{ER}). The fitted values continue to represent cash flow shocks (r^{CF}), while the residuals (r^{RES}) contain discount rate shocks and deviations of conditional expected returns that are month-specific from unconditional expected returns.

Panel A of Table 5 provides descriptive statistics of excess return components resulting from the above return decomposition. By construction, average residual returns are equal to zero. Expected excess returns (r^{ER}) have the mean (median) of 0.59 percent (0.57 percent) per month. About 12 percent of implied raw expected returns (r^{ER} plus the risk-free rate) are negative, which could be due to intercepts absorbing *ex post* on-average negative discount rate news for individual firms during the estimation period. The next section explores potential biases arising due to cross-sectional variation in discount rate news. Panel B of Table 5 provides the results of return decomposition within deciles of *DD Measure*. The expected returns are on average 0.61 percent per month higher for firms in the highest *DD Measure* decile, compared to firms in the lowest *DD*

---

[25] The premiums obtained in the second stage of the two-stage test should be equal to the average abnormal return on the factor, so the significant premiums reported in this section may seem inconsistent with the insignificant abnormal returns on *AQ Factor* in Table 1. The inconsistency is due to the fact that the factor returns reported in Table 1 are contaminated by cash flow shocks. When I reconstruct *AQ Factor* using returns excluding cash flow shocks, the abnormal returns on *AQ Factor* are consistent with the premiums reported in this section.

[26] The two-stage analyses reported in this section use equal-weighted portfolio returns. As discussed earlier in Section IV, equal-weighting is preferable for detecting the effects of accrual quality given that the quality of accruals is more important for smaller firms with less saturated information environments. The untabulated results confirm that the difference in both the total returns and returns excluding cash flow shocks between the poor and the good accrual quality firms is higher for smaller stocks compared to larger stocks. Value-weighting under-emphasizes the returns on the small stocks, which biases the tests against finding an accrual quality premium. When I replicate the analyses using value-weighted portfolio returns, the premiums on *AQ Factor* are smaller and not statistically significant.

The table reports the results of alternative firm-specific return decomposition and asset-pricing tests based on unconditional expected returns from this decomposition for a sample of 75,026 observations over the 1970 to 2006 period.

Panel A contains descriptive statistics for returns decomposed using time-series regressions of excess returns on earnings surprises (*SURP*). The fitted values from these regressions represent cash flow shocks ($r^{CF}_{i,t+1}$), and the intercepts represent unconditional expected returns ($r^{ER}_{i,t+1}$). Residual returns ($r^{RES}_{i,t+1}$) are reported separately. The regressions are based on at least 72 monthly returns.

Panel B reports means of earnings surprises (*SURP*), total excess returns, cash flow shocks ($r^{CF}_{i,t+1}$), unconditional expected returns ($r^{ER}_{i,t+1}$), and residual returns ($r^{RES}_{i,t+1}$) by *DD Measure* decile. The average differences between earnings surprises and returns in the bottom and top deciles of accrual quality are reported in the row "10 − 1." The two-sided p-values for the return (earnings surprise) differences are computed using the Fama-MacBeth approach with a Newey-West correction with six lags.

Panel C contains coefficient estimates from the pooled regressions:

$$(r^{NCF}_{i,t+1}) = \text{Intercept}_t + q_t RDD_{it} + \text{Controls} + \varepsilon_{it},$$

where ($r^{NCF}_{i,t+1}$) denotes the realized return excluding cash flow shocks for stock i and month t+1; RDD_{it} is the decile rank based on *DD Measure*. All other variables are as defined in Table 1.

Panel D reports regression coefficients from the pooled regressions based on the portfolio excess returns excluding cash flow shocks and the full-period factor betas:

$$\overline{r^{ER}_i} = \text{Intercept} + \hat{b}^{AQ}_i \lambda^{AQ} + \hat{b}^{MktRf}_i \lambda^{MktRf} + \hat{b}^{SMB}_i \lambda^{SMB} + \hat{b}^{HML}_i \lambda^{HML} + \varepsilon_{it},$$

where $\overline{r^{ER}_i}$ is the average excess return excluding cash flow shocks on portfolio i calculated using 444 monthly portfolio returns, and $\hat{b}^{AQ}_i$, $\hat{b}^{MktRf}_i$, $\hat{b}^{SMB}_i$, and $\hat{b}^{HML}_i$ are full-period factor betas estimated by regressing excess portfolio returns on factor returns.

The panel partitions refer to three types of portfolios: (1) "25 B/M and Size Portfolios" are based on quintiles of the book-to-market ratio and size; (2) "100 *DD Measure* Portfolios" are based on percentiles of *DD Measure*; and (3) "64 B/M, Size, and *DD Measure* Portfolios" are based on quartiles of the book-to-market ratio, size, and *DD Measure*.

All returns are reported in percentages. Details of earnings surprises (*SURP*) estimation are in Appendix A.

Each regression is based on a pooled sample of firm-specific (portfolio-level) returns and includes (untabulated) time fixed effects. p-values reported in parentheses are based on standard errors clustered by firm and year (Petersen 2009).

Measure decile. The difference is both statistically and economically significant, amounting approximately to 7.32 percent per annum.

Panels C and D of Table 5 report the results of asset-pricing tests based on unconditional expected returns. Because each firm in the sample has a single expected return estimate, traditional asset-pricing tests that rely on the assumption of zero time-series correlation in returns can no longer be used. Instead, I estimate pooled regressions of returns on risk characteristics or factor loadings with time fixed effects and standard errors double-clustered by firm and year.

The premiums on excess returns unadjusted for cash flow news, reported in the first partition of Panels C and D, are not statistically significant in any characteristic- or factor-loading based tests. In contrast, the results based on unconditional expected returns unambiguously suggest a positive and statistically significant premium for accrual quality after controlling for conventional risk characteristics and factors. The coefficient on *RDD* in Panel C is 0.04, which corresponds to the difference in returns between the highest and the lowest deciles of *DD Measure* of 4.3 percent per annum (0.04 percent × 9 × 12). The estimates of the *AQ Factor* premium in Panel D range from 0.30 percent to 0.35 percent monthly (3.6 percent to 4.2 percent on annualized basis). Overall, the results from the alternative return decomposition are consistent with accrual quality being a priced risk factor.

Discount Rate Shocks

The proposed methodology does not control for the second component of unexpected returns, the discount rate shocks arising due to revision in the expectation of future discount rates. To the extent that discount rate shocks are positively correlated with *DD Measure*, the results in the paper are biased in favor of finding a significant accrual quality premium. To provide empirical evidence on the direction of discount rate shocks, I estimate the changes in three commonly used risk measures—the book-to-market ratio, Altman's (1968) Z-Score, and CAPM beta—by *DD Measure* decile. The changes are estimated over the same period as the realized returns (within one year of estimating *DD Measure*).

The results in Table 6 show that firms in the highest *DD Measure* decile with the poorest accrual quality on average become relatively more risky in the immediate future compared to firms in the lowest *DD Measure* decile with the best accrual quality. The book-to-market ratio (CAPM beta) increases 137 (125) percentage points more for firms with the worst accrual quality in Decile 10 compared to best accrual quality firms in Decile 1. The Altman Z-score of the firms with the worst accrual quality in Decile 10 (with the best accrual quality in Decile 1) decreases (increases) on average by 18.7 percent (1 percent), indicating an increased (decreased) probability of bankruptcy. Overall, the empirical evidence suggests that, if anything, firms with poor accrual quality become relatively more risky over time, which is consistent with discount rate shocks being negatively correlated with *DD Measure* and which biases the tests against finding a positive accrual quality premium.

Analyst Forecast Based Earnings Surprise

The earnings surprise measure used in the main analyses is based on a simple time-series model of earnings and relies on single-period earnings news. In this section, I verify that the results are robust to using earnings surprises based on analysts' forecasts pertaining to several consecutive fiscal years. In the spirit of Easton and Monahan (2005), I use realized errors in current-year forecasts and revisions in forecasts for one-year- and two-years-ahead earnings to capture earnings news. The details of variable estimation are in Appendix A. I perform cross-sectional return decomposition by regressing monthly excess returns on earnings surprises and forecast revisions, with a nonlinear earnings response model estimated within forecast-revision quintiles.

The untabulated results from the characteristic- and factor-loading-based tests are similar to those reported in Tables 3 and 4. As a characteristic, accrual quality commands a significant premium of 0.07 percent (0.05 percent) per month based on the linear (nonlinear) return

TABLE 6

	(0.00)	(0.00)	(0.00)	(0.00)	(0.00)	(0.00)

The table reports average proxies for the level of risk and the change in risk for a sample of 92,145 firm-year observations with fiscal years ending in 1970 to 2006.

The average differences between the returns in the bottom and top deciles of accrual quality are reported in the row "10 − 1." The two-sided p-values for these differences are computed using the Fama-MacBeth approach with a Newey-West correction with six lags.

Variable Definitions:

$BETA_t$ = CAPM beta estimated using five years of data ending the most recent December;

$BMRATIO_t$ = ratio of the book value of equity to the market value of equity, where book value is stockholders' book equity plus deferred taxes minus the book value of preferred stock, and the market value of equity is as previously defined;

$ALTM_t$ = Altman (1968) Z-score, which is inversely related to the probability of bankruptcy;

$\%\Delta BETA_{t+1}$ = percentage change in *BETA*, calculated as $(BETA_{t+1} - BETA_t)/|BETA_t|$;

$\%\Delta BMRATIO_{t+1}$ = percentage change in *BMRATIO*, calculated as $(BMRATIO_{t+1} - BMRATIO_t)/|BMRATIO_t|$; and

$\%\Delta ALTM_{t+1}$ = percentage change in *ALTM*, calculated as $(ALTM_{t+1} - ALTM_t)/|ALTM_t|$.

decomposition before controlling for the market value of equity. The significance disappears after controlling for the market value of equity. The premium on *AQ Factor* is statistically significant after controlling for the three Fama-French factors and ranges from 0.51 percent to 1.71 percent per month depending on the return decomposition model and portfolio partitioning.[27]

Additional Robustness Checks

The analyses reported in Section IV are based on the *DD Measure* that is lagged one year relative to the measure used in CGV. The results are robust to using the non-lagged *DD Measure*.

---

[27] The analysis in this section is subject to the sample-selection bias due to constraints imposed by I/B/E/S coverage availability (the sample starts in 1981 and contains only 34,929 firm-years). Importantly, *AQ Factor* commands a statistically significant (although at least 30 percent lower) premium within the I/B/E/S sample even before controlling for cash flow shocks in two out of three portfolio partitions from Table 4. Performing firm-specific return decomposition within the I/B/E/S sample would further reduce the sample to 28,393 firm-years, with attrition especially pronounced in the two top *DD Measure* deciles, where only 18 percent of observations from the main sample are retained. Such extreme attrition reduces the power of the tests and complicates making inferences. Accordingly, I do not perform firm-specific decomposition in this section.

The premiums on *DD Measure* and on *AQ Factor* remain similar in magnitude and statistical significance across all test specifications.

As in CGV, the characteristic-based asset-pricing tests (reported in Table 3) are based on decile ranks of *DD Measure*, which increases the statistical power of the tests by mitigating the influence of errors in the estimated *DD Measure*. I verify that the characteristic-based results are robust to using the raw *DD Measure*, which represents a more stringent test with potentially lower power. The untabulated results are qualitatively similar to those reported in Table 3. The premiums on *DD Measure* are significant after controlling for other risk characteristics only when cash flow shocks are excluded using a firm-specific earnings response model.

CGV also perform the two-stage analysis using individual stock returns and factor loadings. I replicate the two-stage tests for the stocks with at least 30 non-missing monthly returns. The untabulated results based on returns unadjusted for cash flow news show that the premium on the individual *AQ Factor* beta is not statistically significant, similar to CGV results. After excluding cash flow shocks estimated using the cross-sectional linear (nonlinear) earnings response model, the premium on *AQ Factor* is equal to 0.25 (0.40) with a p-value of 0.13 (0.06). The premiums are similar in magnitude but no longer statistically significant when the firm-specific return decomposition is used to estimate cash flow shocks. However, interpretation of these results is complicated by the likely lower power of the tests based on individual stock factor loadings.

In addition, the results are robust to including a decile rank of signed accruals in characteristic-based regressions, suggesting that the results are distinct from the Sloan (1996) accrual anomaly. The results from these regressions are also robust to including a decile rank of the operating cash flow variance, which is a measure of operating risk (Liu and Wysocki 2007), as an additional control variable.

VI. METHODOLOGY LIMITATIONS

The proposed return decomposition methodology is subject to several limitations. First, it does not control for discount rate shocks, i.e., the portion of returns due to changes in the expectation of future discount rates. Although the analysis performed in Section V suggests that omitting discount rate shocks is unlikely to bias accrual quality premium estimates upward, discount rate shocks may represent a correlated omitted variable in other settings. Not controlling for discount rate shocks also limits the interpretation of average magnitudes of returns excluding cash flow shocks. Although discount rate shocks explain a small portion of variation in returns on individual stocks, the corresponding portion of returns is much higher for portfolios of stocks (Vuolteenaho 2002). As a consequence, after excluding cash flow shocks, the *average* return for a sample of firms may, to a significant extent, consist of discount rate news.

Second, under the earnings response coefficients framework, where discount rates are considered constant, the relation between cash flow shocks and realized returns is linear. However, in general, returns and cash flow shocks are not linearly related. Incorporating stochastic discount rate shocks in the earnings response coefficient framework may be a fruitful path for future research.

Third, in the presence of information signals about future payoffs arriving from outside the accounting system, the relation between returns and one-period earnings surprises is positive only under restrictive assumptions, and is generally nonlinear (Antle et al. 1994). Although nonlinear and firm-specific earnings response estimation addresses this concern to some extent, it does not solve the problem completely. Overall, it is impossible to fully address Antle et al.'s (1994) criticism within the proposed methodology, since at a minimum it would require incorporating signals from outside the accounting system.

VII. CONCLUSIONS

Using a simple methodology that follows from the earnings response coefficient framework, I estimate the cash flow shock portion of realized returns and document that, over the past 37 years, poor accrual quality firms, i.e., firms with high *DD Measure*, systematically experienced more negative cash flow shocks compared to good accrual quality firms, i.e., firms with low *DD Measure*. When asset-pricing tests use realized returns that exclude cash flow shocks estimated using the more powerful return decomposition methods, the low accrual quality stocks (stocks with higher accrual quality factor betas) are associated with significantly higher expected returns compared to the high accrual quality stocks (stocks with lower accrual quality factor betas).

Evidence that the accrual quality measure based on the Dechow and Dichev (2002) model is priced by the market is important due to both the theoretical appeal of the model and its widespread use in accounting research. The model is especially appealing in the asset-pricing context because it captures an important feature of accrual and earnings quality, errors in accrual estimates, and subsequent reversals in these errors. Such errors are related to the concept of accounting information precision, which maps into theoretical work on the link between the cost of capital and information quality (e.g., Lambert et al. 2007).

The paper also has implications for research that uses realized returns to proxy for the cost of equity, and suggests a simple method to identify correlations with future cash flow shocks and to control for the effects of such shocks. The results underscore the importance of excluding cash flow shocks to avoid biased risk premium estimates.

APPENDIX A
EARNINGS SURPRISE PROXIES

Earnings Surprises Based on Time-Series Model

The earnings surprise variable, *SURP*, is calculated as actual earnings minus expected earnings, that is, $EARN_{it+1} - E_t(EARN_{it+1})$. Expected earnings are estimated from a simple statistical model that is based on the assumption that annual earnings follow a first-order autoregressive process (AR1):

$$EARN_{it+1} = \beta_0 + \beta_1 EARN_{it} + \varepsilon_{it+1},$$

where $EARN_{it}$ denotes earnings before extraordinary items (Compustat #18) for firm *i* during fiscal year *t*, scaled by the book value of equity at the beginning of fiscal year *t* (Compustat #60).

Estimation of expected earnings is performed in two stages: (1) the predictive coefficients $\hat{\beta}_0$ and $\hat{\beta}_1$ are obtained by estimating the model cross-sectionally over the previous year (e.g., using $EARN_{it-1}$ and $EARN_{it}$); and (2) the earnings prediction is calculated by combining the estimated coefficients with variable values:

$$E_t(EARN_{it+1}) = \hat{\beta}_0 + \hat{\beta}_1 EARN_{it}.$$

For example, the 2005 earnings predicted at the end of 2004 are calculated using the values of predictive variables for fiscal 2004 and coefficients estimated by regressing earnings from fiscal 2004 on earnings from fiscal 2003. The expected earnings are then converted to an absolute basis by multiplying by the book value of equity. *SURP* for each month is scaled by the beginning-of-month market value of equity.

Earnings Surprises Based on Analysts' Forecasts

In the spirit of Easton and Monahan (2005), I use three variables based on analysts' forecasts to capture earnings news released during fiscal year *t*+1.

(1) Forecast error on the EPS_t forecast made at the end of fiscal year *t*. It captures a revision in expectations of future earnings that occurs in year *t*+1 due to announcement of realized earnings for fiscal year *t*.
(2–3) Revisions in one- and two-year-ahead earnings forecasts ($FREV_{it+1}$ and $FREV_{it+2}$), calculated as:

$$FREV_{it+n} = FEPS_{it+1,t+n} - FEPS_{it,t+n},$$

where: $FEPS_{it,t+n}$ denotes the *n*-years-ahead consensus EPS forecast from I/B/E/S at the end of fiscal year *t*.

The forecast errors and forecast revisions for each month are scaled by the beginning-of-month stock price.

BOOK REVIEWS

Stephen A. Zeff, Editor

Editor's note: Two copies of books for review should be sent to the Book Review Editor: Stephen A. Zeff, Rice University, Jesse H. Jones Graduate School of Business, 6100 Main St., Houston, TX 77005. The policy of *The Accounting Review* is to publish only those reviews solicited by the Book Review Editor. Unsolicited reviews will not be accepted.

WILLIAM H. BEAVER, MARIA CORREIA, and MAUREEN F. MCNICHOLS, *Financial Statement Analysis and the Prediction of Financial Distress*, Foundations and Trends® in Accounting (Hanover, MA: now Publishers Inc., 2011, ISBN: 978-1-60198-424-1, vol. 5, no. 2, pp. x, 79).

There is no doubt that predicting and managing corporate financial distress have become increasingly important parts of doing business and making investing and lending decisions, not only in the U.S., but also throughout the world. Altman and Hotchkiss (2006) note that, as businesses and bankruptcy laws have both become more complicated, the need for professionals with specialized skills has grown as has the demand for academic research into the prediction of financial distress. *Financial Statement Analysis and the Prediction of Financial Distress*, by William Beaver, Maria Correia, and Maureen McNichols (hereafter, BCM), provides an exceptionally well-written overview of the three main aspects of the academic financial distress prediction literature: the dependent and explanatory variables that different researchers have used, the statistical methods they have used, and the way in which they model financial distress. Although the monograph is written so that practitioners, students, instructors, and researchers will all find it very useful, it concludes with suggestions for future research and thus promises to be used by scholars for years to come. I also believe that some of the ideas in the monograph can be extended and used to shape research designs in the growing areas of fraud prediction and litigation risk estimation.

The monograph begins with a discussion of the somewhat ill-defined concept of financial distress and its frequently used counterpart, insolvency. This is a good discussion to have at the beginning, because the way in which empirical prediction models are structured and used depends on exactly what the researcher is trying to predict. BCM follow this discussion with an intuitive explanation of likelihood ratios and loss ratios and their interpretation. The discussion of loss ratios is particularly well-written and provides a clear picture of the complexity of a lender's decision-making process and how output from a prediction model can affect not only the decision to lend but also the structure of the loan itself.

BCM then begin their discussion of the role of financial statement analysis in bankruptcy prediction. They outline some of the limitations of accounting information (e.g., much of it is backward looking and not timely) and then provide a brief overview of early univariate analysis and the evolution of financial distress prediction models that rely on financial statement ratios, starting with the Index of Credit Strength introduced by Wall and Dunning in 1928. BCM note that this "model" never gained popularity, largely because of Wall and Dunning's arbitrary assignment of weights to the eight included ratios. Despite this, accounting-based models have continued to be developed without an explicit theory to guide their design, although BCM note that a number of researchers have used out-of-sample testing, in part to provide indirect evidence on the stability of the weights that their empirical models produced. BCM then describe and contrast the methodologies used in the currently most well-known, early financial-statement-based prediction models: the multiple regression approach and univariate analysis in Beaver (1965, 1966), the multiple discriminant analysis in Altman (1968), and the conditional logit analysis in Ohlson (1980). They then discuss the advantages of hazard analysis, a technique that Shumway (2001) introduced into the literature a decade ago. The section ends with helpful discussion and graphical descriptions of key financial statement ratios and what we have learned about their relation to financial distress through these models.

One of the early, and enduring, criticisms of financial-statement-based prediction models is that stock price and other market-based measures summarize a more comprehensive set of information than accounting ratios and therefore should be at least as useful in predicting financial distress. Further, academic research in finance (BCM mention Merton [1974] and Black and Scholes [1973]) provides a framework for estimating the probability of distress from the market prices of securities. In the next section of the monograph, BCM describe some of the market-based variables that have been used in prior research, but also note that, although using market-based variables is intuitively appealing, it is "nontrivial" to extract a useful probability of bankruptcy or distress from these measures, particularly in the light of the evidence that prices are not semi-strong efficient as once believed.

In order to compare and contrast the usefulness of accounting-based versus market-based prediction models, BCM next assess the predictive ability of an accounting-based model, a market-based model, and a model that contains both accounting- and market-based variables. The choice of accounting variables was guided by recent research, as was the decision to used hazard analysis as the estimation technique for this comparison. In this part of the monograph, the reader learns more about the "nuts and bolts" of current state-of-the-art prediction models: the variables to include, how those variables are measured, and how the models compare, drawing on the analysis in recent work by BCM and a published paper, Beaver et al. (2005). The careful and clear comparisons in this section are likely to be useful to a broad range of readers, but will certainly be helpful to researchers who are interested in how the various models perform in a relative sense and how methodological choices affect their performance.

Before providing directions for future research, BCM end their overview of the different prediction models by describing a number of issues that affect financial distress prediction, some of which are particularly interesting and deserve a closer look. For example, does the exercise of discretion both within and outside of generally accepted accounting principles affect the relative usefulness of accounting-based versus market--based measures? Similarly, does the presence of unrecognized intangibles affect predictive ability? BCM pose these questions as well as others but do not stop with raising the questions. They also summarize currently available evidence on the effect of certain accounting characteristics on the models' performance and then move on to other alternative research design issues.

BCM end the monograph with a number of suggestions for future research, many of which are likely to move the bankruptcy prediction literature in accounting forward and have an impact on other related research streams. For example, how do financial ratios based on IFRS affect the predictive ability of the popular models? How do bankruptcy prediction models perform relative to auditors' going concern judgments in the post-SOX environment? I found this section of the monograph to be particularly thought-provoking.

Overall, BCM have produced a valuable resource for anyone looking to learn more about the prediction of financial distress and its evolution. Their monograph is written in a way that makes it accessible to a broad range of readers, from doctoral students and researchers who are interested in the evolution of prediction models as well as the current state of the art to regulators and practitioners who wish to learn more about forecasting financial distress in corporations. It is likely to be a resource that many of us will rely on for years to come.

TIM BÜTHE and WALTER MATTLI, *The New Global Rulers: The Privatization of Regulation in the World Economy* (Princeton, NJ: Princeton University Press, 2011, ISBN 978-0-691-14479-5, pp. xvii, 301).

What drives global standard setting? Who are the new global rulers, and what constitutes their power? Can individuals or firms affected by global rules influence the process of global rule-making and effectively articulate their interest? Under what circumstances does global rule-making reflect the needs of domestic constituents? Tim Büthe and Walter Mattli, two political scientists, pose these questions in their monograph, which broaches the issue of global rule-making in a broad sense. However, their research concentrates particularly on two issues: accounting standard setting by the International Accounting Standards Board (IASB) and product standard setting by the International Organization for Standardization and the International Electrotechnical Commission (ISO/IEC).

IASB and ISO/IEC rule-making share a very similar characteristic. They are executed by what the authors call delegated, private focal institutions. Such institutions are regulators that have neither governmental status nor international competitors, due to an exclusive standard-setting authority. Rule-making is, in other words, focused on single, privately organized regulators. Also, the processes of setting rules or standards are very similar. It is common to justify this kind of regulation because of the nature of the respective standards. Those rules regulate rather technical issues and therefore require specific expertise. It is claimed that such standards could be effectively provided only by privately organized authorities. However, the authors claim, and empirically support, that the processes of setting the standards are far from being just "technical." Their research evidence shows that these processes are as political as they are in other areas of regulation.

It is not the aim of the authors to criticize this inherent political nature of global standard setting by private focal institutions. They do not intend to pose legitimacy concerns or to evaluate the efficacy of the processes and the way global ruling is delegated. Rather, the objective of their research is to provide a theoretical framework for this specific way of global rule-making in order to explain how it works and to identify the critical factors for successfully influencing the process of standards development.

The authors test their framework with a large set of empirical data collected from two multi-country, multi-industry business surveys in Europe and in the U.S., supplemented by a large number of interviews.

They therefore provide the most comprehensive and systematic empirical evaluation of global standard setting so far.

The book has nine chapters and three appendices. Chapter 1 describes the rise of private regulation in the world economy and provides a short overview of the research done by the authors. Chapter 2 places standard setting by private focal institutions into context and describes a typology of global regulation, thereby identifying four principal types of rule-making: competing standard setting by public bodies, competing standard setting by private institutions, non-market-based focal rule-making, and market-based focal rule-making. The authors make clear that both IASB and ISO/IEC standard setting belong to the last category.

In the third chapter, the authors introduce what they call the concept of institutional complementarity. The key idea of the concept is that successful and timely influence of market-based focal rule-making crucially depends on how the institutional structure of domestic standard setting complies with the international one. The more the domestic structure is focused on a single standard setter that has established processes that are organized similarly to the focal international institution, the more likely that domestic constituents ("stakeholders") will exert a successful influence. A focal domestic institution that clearly represents the broad opinion of a country's individuals affected by the international standards will be perceived as the key domestic "player" by the global ruler. When new international standards are to be developed by means of an international due process, the opinion of such an institution will be regarded as highly relevant and uncontested by domestic constituents. The authors characterize such a domestic system as hierarchical with a peak-level national standard-setting body and ascribe high institutional complementarity with the global ruler to the domestic system.

However, domestic systems could also be characterized as rather fragmented, with different institutions responsible for domestic standards and representing different constituents. All of the institutions could take part in the international due process. In that case, the global ruler could be confronted with contested national opinions on the international standard that has to be developed. In such a domestic system, which the authors characterize as non-hierarchical with low institutional complementarity, it is less likely that domestic constituents affected by international standards will successfully influence the international standard setting process.

The authors identify two factors that seem to be tied to institutional complementarity: (1) early access to information and therefore an early participation in the process itself, and (2) effective representation of domestic interests by a strong and uncontested "voice," endowed with sufficient economic resources and structured similarly, as well as providing expertise akin to the global ruler. Indeed, the way that domestic institutions are organized governs whether conflicts between constituents are projected to the international level. For competing domestic institutions, early information could be regarded as exclusive *vis-à-vis* contestants. Institutions might keep this information solely to serve their specific constituents and therefore impede quick information dissemination within the country. If information comes late, then it is difficult to take part in the due process at an early stage. The authors claim, and they prove with anecdotal evidence, that as soon as the global ruler decides on the key principles of a standard—e.g., if an accounting standard reaches the status of an exposure draft—it is difficult, if not impossible, to revise such fundamental decisions. Eventually, a strong domestic standard setter is often regarded as a partner in planning projects, agenda-setting, or even standards development due to the limited recourses of global rulers.

One might claim that such a dichotomy of domestic regulation seems too crude to characterize the variety of regulation systems worldwide. However, the authors concentrate their empirical research in later chapters in such a way as to confirm that this categorization is suitable to describe what constitutes power in global ruling.

In Chapters 4 and 5, the authors describe how their model fits international accounting standard setting, while Chapters 6 and 7 cover global regulation of product markets.

Chapters 4 and 6 start with a brief description of the history of global accounting governance and global market governance through product standards, respectively. In each of the chapters, characterizations of the standard-setting processes follow, indicating the respective importance of early and uncontested participation of national responsible institutions. Though brief, the descriptions are interesting because they show the similarity of global-ruling processes by privately organized focal institutions.

Extremely perceptive are the authors' following characterizations of domestic systems. In accounting regulation, the U.S. domestic system fits tightly to the model of a hierarchical structure, with high complementarity to the standard-setting process of the IASB. The FASB is indeed a strong focal domestic institution, with resources and technical expertise that are the envy of other domestic standard setters. The IASB and FASB work closely together when new standards are to be developed, a fact institutionalized through the Norwalk Agreement, which aims to converge the IFRS and U.S. GAAP. Opposed to that are nearly all of the European systems. Even the British system, whose financial markets are similarly structured to those in the U.S., is rather non-hierarchical, having a sharp fragmentation of institutions competing for members and status, and different accounting philosophies and priorities, reflecting different constituents. Accounting stakeholders in the U.K. seem to approach the IASB individually or through six different professional bodies and not with "one" voice.

The authors also briefly describe the German and the French systems, which differ even more from the U.S. system. Although the harmonization of accounting has been on the European agenda for decades, its institutionalization is far from being a fact. As the authors show, a transnational accounting standard-setting structure does not really exist in Europe. Fragmentation in Europe instead leads to the European endorsement mechanism for newly released IFRS. Compared to the FASB, Europe remains divided on accounting issues. European institutions like the European Financial Reporting Advisory Group (EFRAG) are contested by national standard setters; so Europeans have difficulty in speaking with one voice. Institutional complementarity in Europe is, in other words, low compared to that in the U.S.

Interestingly, the story is reversed for product standard setting. The description of the European and the U.S. systems in Chapter 6 shows a high fragmentation of domestic product standard regulation in the U.S., compared to a rather hierarchical and focused institutional setting in Europe. The European system is characterized by an effective mechanism for broad preference aggregation at the transnational, as well as at the domestic, level. Coordination takes place under the umbrella of a single domestic institution, supplemented by private sector organizations all over Europe that reinforce these structures. The European system is hierarchical and strongly complementary to the structures of ISO/IEC. The U.S. system lacks this complementarity, because a variety of domestic institutions compete nationwide for constituents. Market globalization amplifies the need for U.S. firms to comply with international product standards in order to keep their market shares. However, the institutional fragmentation impedes U.S. firms from effectively taking part in the process of international standards development. Due to the contesting domestic institutions in the U.S., it is difficult for U.S. constituents to speak with a single voice.

In Chapters 5 and 7, the authors explicate two large and comprehensive survey designs for global accounting standard setting and product standard setting, respectively. The question they pose in Chapter 5 is whether Europeans are aware of their institutional disadvantage in global accounting regulation and whether institutional fragmentation is the reason. In essence, accounting experts, that is, financial executives in European and U.S. firms, are asked about their satisfaction with the IASB and their involvement in the standard setting process. The survey is concentrated on the preparers of financial statements, not on the users. The design is similar for product markets (Chapter 7), because the survey here concentrates on technical experts in European as well as in U.S. firms. However, while such a design makes perfect sense for product markets, one might ask why other key constituents affected by accounting standards, e.g., financial analysts or other users, are not part of the survey. The authors may justify a concentration on preparers by saying that users, although affected by the rules, traditionally do not play a significant fole in the standard-setting process. Nonetheless, it seems that the authors' intention was to keep the two surveys closely comparable and therefore confined both sets of studies to company experts.

The research approach in Chapter 5 (Chapter 7) is to identify whether U.S. (European) firms are more in favor of the IASB rule-making (ISO/IEC rule-making) process than their European (U.S.) counterparts. The authors start with striking anecdotes on accounting and product-standard regulations, respectively, which indicate that their theory on institutional complementarity as the main driver for successful involvement in the regulation processes might hold empirically. In their systematic analyses, the authors use four maximum likelihood regression models. The dependent variable reflects the respective overall satisfaction of the surveyed experts with their involvement in the IASB or ISO/IEC due processes. Independent variables are several factors the authors presume to significantly affect a firm's perceived success to influence the standards-setting processes.

In a first comparison, the authors find that overall satisfaction with IASB rule-making is significantly higher for U.S. firms than for their European counterparts (Chapter 5). This result is related to survey questions on the effectiveness of the IASB in achieving specific objectives (e.g., transparency, capital market stability, comparability) and on its governance (e.g., accountability of the IASB, timeliness of up-dating, accessibility of

IFRS, due process in general). The perceived success of influencing IASB standard setting (the dependent variable "power and influence") is regressed on six explanatory control variables derived from corresponding survey questions (firm size, direct contacts with expert groups within the IASB, attempted influence via comment letters, timing of information received, frequency of influence attempts, and attempted influence via government). Testing the four regression models, the authors find that all variables have a strong explanatory power. However, in order to test their theory, the authors integrate a dummy variable with 1 = U.S. firm and 0 = other, which enhances the significance of each model considerably. The authors also document significant increases in the perceived overall influence on the IASB standard setting if the dummy is 1, that is, for U.S. firms. In other words, constituents in the U.S., a country with a domestic standard-setting system that highly complements the IFRS system, feel better served by the IASB than constituents in Europe, where complementarity of domestic standard setting with the IFRS system is low.

The research approach on the ISO/IEC rule-making (Chapter 7) is very similar to that on the IASB regulation. As expected, U.S. firms' overall satisfaction with global standards on product markets is significantly lower. The authors conduct a regression analysis similar to that on the IASB. The dependent variable is the perceived influence on international product standards, while independent variables are various control factors that the authors presume to affect the perceived influence on the rule-making of ISO/IEC. All factors have a significant influence in four alternative models. In an analogy to the study on accounting regulation, a dummy variable with 1 = European firm and 0 = other enhances the significance of the models, and increases the overall satisfaction with influence on international standards in product markets. The high complementarity of European product standard setting with ISO/IEC rule-making seems to be the driving factor. Interestingly, U.S. firms with subsidiaries in Europe show a higher overall satisfaction with international rule-making than those without. The authors attribute this finding to the fact that those firms are able to execute their influence via their European subsidiaries, that is, in a system that better complements international rule-making than the U.S.

In Chapter 8, the authors discuss their results and draw some important conclusions. Institutional complementarity seems to be crucial in transnational standard setting by focal institutions. Their comprehensive survey provides compelling evidence of their theory and invaluably enhances our understanding of international standard setting. As they claim in Chapter 1 (p. 10), the monograph is the result of eight years of extensive research on this highly relevant topic. However, the authors are also careful in their conclusions. They stand afar from drawing any normative claims. Neither do they regard high complementarity systems as superior in every sense, nor do they overlook legitimacy concerns with regard to international standard setting by focal institutions. The authors can nonetheless take credit for having developed a convincing theory on the main drivers of power within this specific and widespread phenomenon of global ruling.

The book is, without a doubt, highly recommended. While it is primarily intended for scholars, it provides very interesting insights for anyone interested in how global standard setting works, in its historical, political, and socio-economic background, and in its significance for global governance in general. The conclusions drawn by the authors contribute to the literature in political science, sociology, law, economics, and business science. Accounting scholars should be particularly interested because a major focus of the research is standard setting by the IASB.

GARY PREVITS, PETER WALTON, and PETER WOLNIZER (editors), *A Global History of Accounting, Financial Reporting and Public Policy: Americas* (Bingley, U.K.: Emerald Group Publishing Limited, 2011, ISBN 978-0-85724-811-4, pp. xi, 160).

Each of the five chapters of this book covers the history of accounting in a major Western Hemisphere country: Argentina, Brazil, Canada, Mexico, the U.S., and Canada. These nations represent a well-balanced cultural portfolio of British, Portuguese, and Spanish origin, which provides an interesting backdrop for examining the evolution of accounting in the hemisphere. With the exception of Canada and Mexico, the chapters are authored by accounting faculty at major universities in the selected countries. Chapter 5 is dedicated to the United States and is jointly written by Stephen Moehrle and Jennifer Reynolds-Moehrle, both accounting professors at the University of Missouri–St. Louis. Given the space limitations for this review and the familiarity that most readers of *The Accounting Review* have with U.S. accounting, I will limit my comments on this chapter to observing that it is an excellent synopsis of the history of U.S. accounting. It could be required reading for all accounting majors.

Chapter 1, "Argentina," written by Sandra Aquel and Mabel Mileti, accounting professors at the Universidad Nacional de Rosario in Argentina, begins by taking the reader back to the 15th century when there really was no national economy, little import/export activity, and no significant impulse for accounting development. Eventually, growing colonial trade with Europe in the late 18th century, and the emergence of conveniently located large cattle-raising ranches as well as the advent of the railroads in the 19th century led to the growth of international commerce, large diversified businesses, national legislation, a governmental budgetary system, a monetary system, and the increased use of contracts that obligated debtors to keep books in balance and report on them as requested by creditors.

Most of the chapter on Argentina is dedicated to reporting the history of the country's mechanisms for issuing "professional" accounting standards by the accounting profession within a legal system that afforded the profession wide latitude in its choices. There were also "legal" standards issued directly by the national and provincial governments, as well as "corporate" accounting standards issued by regulatory bodies. Various accounting associations existed since 1941; every few years they would hold an assembly in which standards may be adopted, but this system of holding meetings for the adoption of accounting standards eventually gave way to the formation of successive professional bodies specifically charged with that task. Accounting principles then had to be approved by provincial accounting associations as well as by those representing Buenos Aires, the country's very large capital city and predominant economic center. Achieving consensus across these different organizations was not always easy, an important issue that impeded progress and that the authors fail to mention in their discussion. Consequently, it was only in 2005 that a body of principles (a "technical agreement") was finally adopted countrywide by all of the professional organizations. Further, motivated by globalization and recognizing the advantages of international standards, the profession, led by the Argentinean Federation of Professional Councils in Economic Sciences (FACPCE), has now adopted IFRS, subject to modifications based on local needs.

By focusing primarily on the history of the mechanisms used in issuing "professional" accounting standards, the chapter on Argentina has the narrowest focus of all of the chapters. The authors could have discussed many other issues of interest, such as specific accounting principles and practices (particularly in dealing with inflation, which reached a rate of 20,000 percent in the early 1990s), foreign influences on Argentinean accounting, standards for professional practice, the social status of the profession, etc. Further, there is no discussion of the colonial accounting systems that were employed early on and for a long time by the representatives of the Spanish crown and institutions such as the Catholic Church and its Jesuit missionaries (see the "Mexico" chapter for this information). Also, while sometimes at odds because of the Perón dictatorship and more recently the Falkland Islands sovereignty conflict, Argentina and Britain have maintained a very close cultural and economic relationship for centuries following the Spanish colonial era. The long-standing Harrods department store in Buenos Aires, British ranches, clubs, and even the country's pre-eminence in British sports like football (soccer), rugby, tennis, and polo (consistent world champions) and many other venues and endeavors are evidence to this day of a British legacy firmly entrenched in Argentina's economy and culture. It would be unthinkable for the British not to influence local accounting standards and practices—yet there is no mention in the chapter of the doubtless important contribution that British managers and other foreign influences from large multinational businesses and accounting and auditing firms must have made to the development of Argentinean accounting. There is also no discussion of the professional formation and certification of accountants (for a long time trained primarily in economics rather than in accounting and still not having to pass a professional examination or meet continuing education requirements), their social status (also for a long time relegated to lowly bookkeepers), and the threat of legal liability (much less of a concern than in the U.S. or Canada).

Chapter 2, "Brazil," is written by L. Nelson Carvalho, a professor at the Universidade de São Paulo, and Álvaro A. Ricardino Filho, a professor at Pontificia Universidade Católica de São Paulo. It is the second longest chapter (24 pages of text versus, for example, 17 for "Argentina") and is broader in scope and richer in depth and detail than Chapter 1. The content again is classified into periods that affected accounting, although these periods are based primarily on the country's political developments rather than on the accounting profession's stages of development. Political periods discussed include the country's colonial period, its years as the seat of the Portuguese throne (when seeking refuge from an impending French invasion under Napoleon, the royal family of Portugal and 10,000 courtiers and sympathizers moved to Rio de Janeiro in 1808 and stayed there until 1821), its subsequent years as an independent kingdom from 1822 to 1889, and three phases as a republic, its current status. From its early stages, the country's economy was more diversified than Argentina's, because, in addition to cattle, it produced sugar, coffee, and minerals.

Throughout Brazil's first 300 years of history, accounting practices "had as their sole purpose to report taxes to the Portuguese crown, usually ranging from 10% to 20% of gross proceeds of any kind of revenue or production" (p. 26). Legislation adopted in 1860 for the first time required financial institutions to present financial statements, prepared according to prevailing standards, to shareholders and the government. The remainder of the chapter is a fairly detailed narrative about accounting practices and requirements, the development of accounting standards, the evolution of the accounting profession in response to political and economic events (including the significant impact of inflation in the early 1980s), and a discussion of Brazil's decision, which was overturned by a law in 2007, to allow financial accounting practices to differ from those used for tax purposes. That same law in 2007 mandated IFRS to be applied in the preparation of financial statements. Currently, the Committee on Accounting Pronouncements issues accounting standards and endorses IFRS, which have to be followed by listed companies as regulated by the country's Securities and Exchange Commission.

Chapter 3, dedicated to Canada, is written by Chester H. Brearey, who teaches at Siena College in New York State. Four time periods are identified: early accountability (1850–1890), accountancy (1891–1920), consolidation and U.S. influence (1921–1951), and delegation of standard setting (1960–2010). Britain and the United States have significantly influenced the development of Canadian standards, although at times the latter has been in a leading position. Somewhat similar to the Argentinean experience, the development of the railroad industry is mentioned as an important nation-building factor, which likely fostered the accounting development of these large countries. Development of accounting in Canada has evolved without major intervention by the country's federal government, which has left the "virtually unrestricted government delegation of standard setting authority to the profession (Canadian Institute of Chartered Accountants [CICA])" (p. 51). Over time, the CICA's accounting and auditing standards-issuing functions were delegated to a series of committees, presumably searching for wider acceptability of standards. Eventually, the accounting principles-issuing function was passed on to the Accounting Standards Board. In 2006, this Board opted for the convergence of Canadian principles with IFRS, which are now required for public companies.

Chapter 4 concerns Mexico and is written by Ikseon Suh and Sandra Minaburo. Professor Suh teaches at Marquette University in the United States and Professor Minaburo is a faculty member at the Instituto Tecnológico Autónomo de México. The chapter is divided into five stages: (1) pre-Spanish conquest, (2) post-Spanish conquest, (3) transitional era, (4) era of the Mexican Institute of Public Accountants (Instituto Mexicano de Contadores Públicos, or IMCP), and (5) the convergence era.

The historical perspective reflected in this chapter stretches the furthest into the past. This is the most interesting chapter from an anthropological point of view, even though the space dedicated to the pre-Spanish period is only a little more than one page. Aztec currencies were cocoa beans, cloth, shells, and powdered gold; "a sack of 8,000 cocoa beans represented the most frequently used unit of measurement, known as '*xiquipilli*'" (p. 80). Taxes were levied by the Aztec government on inhabitants of conquered cities in exchange for protection, and were collected and recorded by government representatives, or "*calpixques*," who then submitted them to stewards in major cities who also had to keep records of the inflows and outflows. Examples of these early accounting records, though very rare, are kept in museums in Oxford, U.K. and Mexico City, Mexico.

The section on Mexico as a Spanish colony includes an excellent discussion of the accounting books, such as the *book for alms and favors* and the *book for tax collection*, kept by the Crown's representatives for a variety of economic and social functions that they performed. The colonial era was followed by the era of independence. Successive commercial codes were issued that eventually (in 1889) required merchants to maintain a *journal*, *ledger*, and a *book of inventories and balances*, as well as a series of other records. This period was followed by the era of the Mexican Institute, which in 1964 assumed the accounting rule-making authority for the country. An important item within this era is the discussion on inflation accounting. Finally, during the current era of convergence, the Consejo para la Investigación y Desarrollo de Normas de Información Financiera (CINIF), the Council for Research and Development of the Principles of Financial Information, has been given responsibility for the development and issuance of accounting standards. Beginning on January 1, 2012, Mexican public companies are preparing financial statements in conformity with IFRS under CINIF's guidance. Although the chapter does use relatively more space than others on the development of the accounting profession, it fails to mention that the Mexican equivalent of a U.S. CPA and a Canadian CA, the *contador público certificado* (CPC), was instituted only in 1988, with continuing education and other requirements. This and other changes resulted from Mexico's membership in NAFTA and subsequent international commitments, such as with the U.S.'s National Association of State Boards of Accountancy (NASBA).

Overall, it is apparent the authors were given considerable latitude in selecting the format for their contributions. This is both a weakness and strength, because, while it makes it a bit more difficult to sort through and compare the chapters' contents, which vary in depth and breadth, it adds freshness and uniqueness to each chapter. Nonetheless, the chapter on Argentina, in particular, could have been enriched with some additional content, as commented on above. Also, the reader should keep in mind that, until just a few years ago, the primary purposes of accountability in Latin America were reporting to owners and creditors, tax compliance, and stewardship and control, rather than providing information to what were until recently tiny local capital markets. Globalization and the need for external investors' financing have favored the adoption of IFRS by the three Latin countries, which, in turn, raises the status of the accounting profession. This effect is likely not as significant in the U.S. or Canada, where relatively larger capital markets and strong accounting professions have been in existence much longer. In conclusion, this is a well-written and well-edited, interesting book that may be used in international accounting classes. The book will also be an excellent addition to any professional library, and will be particularly useful to readers involved in accounting activities in the Western Hemisphere.

OSCAR J. HOLZMANN
Associate Professor of Accounting
University of Miami

GARY PREVITS, PETER WALTON, and PETER WOLNIZER (editors), *A Global History of Accounting, Financial Reporting and Public Policy: Europe* (Bingley, U.K.: Emerald Group Publishing, 2010, ISBN 978-0-85724-671-4, pp. xii, 302).

This volume of essays on ten European countries is the first in a series of four covering the history of accounting, financial reporting, and public policy in larger economies and developing economies. Later volumes will cover the Americas, Asia and Oceania, and Eurasia, Middle East, and Africa.

The goal of the editors of the series is to provide a series of historical source books for a readily converging world of accounting and financial reporting based on the premise in Walton (1995) that it is important to evaluate a country's accounting and financial reporting in the light of its national history. The ten European countries chosen for this first volume are Belgium, France, Germany, Italy, The Netherlands, Poland, Spain, Sweden, Switzerland, and the United Kingdom.

Each essay deals with a single European country and is written by one or two nationals of the relevant country. For the most part the authors structure their essays around developments in particular time periods. The essays by Claude Bocqueraz on France and Alicja Jaruga and Przemysław Kabalski on Poland are good examples of this approach. They also show the different influences on national accounting, including the impact of one country's accounting on another country's accounting.

Bocqueraz identifies three time periods in the history of accounting in France: the end of the seventeenth century to the Second World War, from 1942 to 1973, and from 1973 to the present day. Jaruga and Kabalski identify five periods in the history of accounting in Poland: the fifteenth and sixteenth centuries; the nineteenth and early twentieth century when Poland was partitioned between Austria, Prussia, and Russia; from 1919 to 1939, when Poland was independent; from 1945 to 1989, when Poland was a centrally planned economy; and from 1990 onward after Poland regained its sovereignty.

Bocqueraz explains that the first French accounting requirements were Colbert's ordinance in 1693 and the commercial code in 1807. As other essays explain, the requirements of Colbert's ordinance and the French commercial code were reflected in national codes in, for example, Belgium, Germany, Spain, and Switzerland. Furthermore, as Jaruga and Kabalski acknowledge, this French influence was extended to Poland when, under partition, it was compelled to use the commercial codes of Austria, Prussia, and Russia, each of which had, themselves, been influenced by the French code.

The second period in the history of French accounting was dominated by the creation of the *plan comptable général* (national accounting plan) that provided detailed guidance on the keeping of accounting records and the presentation of financial statements. Bocqueraz explains that the plan reflected the state's need to establish control over the production of accounting information. As a centrally planned economy between 1945 and 1989, the focus of accounting in Poland also shifted to the needs of government statisticians, which meant, according to Jaruga and Kabalski, that Poland eventually turned to the French model.

In the 1980s and 1990s, France and Poland adopted the EC directives, but their experiences of the directives differed. France had participated in the negotiations leading up to the adoption of directives. Bocquerez suggests that that level of harmonization achieved in France was minimal because of the compromises that underlay the directives. Poland joined the European Union after it had regained its sovereignty and long after the directives had been approved. Jaruga and Kabalski relate how the transformation of the economy meant changes to the accounting system. They suggest that the adoption of the directives changed the orientation of accounting in Poland from tax to business.

Other essays also highlight the different experiences of implementing the directives. Mara Cameran and Angela Pettinicchio suggest that their implementation in Italy brought greater regulation, increased comparability, and significantly improved accounting regulation. Carlos Larrinaga and Marta Macías argue that the directives drove an intense process of accounting reform in Spain, which led to a profound transformation in the audit profession and in the audit market. In contrast, Kristina Artsberg relates the disappointments of the Swedish accounting profession with the directives and how one member of that profession described the adoption of the directives as a return to the stone age of accounting.

Most of the essays deal only briefly with the influence of the European Union's IAS Regulation and any broader influences of IAS/IFRS on national accounting and financial reporting requirements. The one exception is Poland, for which the authors deal extensively with the influence of IAS/IFRS on successive revisions to the Accountancy Act and national accounting standards. While Bocqueraz admits to some convergence between French standards and IFRS, she suggests that convergence has been constrained by the French legal and taxation environment.

The link between financial reporting and taxation requirements is dealt with in all of the essays. The reader will soon be aware that the link not only varies among countries, but also that it continues to evolve. Ann Jorissen and Peter Stabel note that Belgium's commercial law of 1913 provided ample opportunity for tax laws to influence financial reporting and valuation practices, but that this opportunity was lost following the decision of the tax authorities to accept all of the rules of the accounting law of 1975 unless the tax law expressly provides otherwise. Kristina Artsberg refers to the extensive recent debates in Sweden about whether to retain a 1928 requirement that taxable profits should be based on accounting profits. Christopher Napier refers to the United Kingdom's earlier position under which entities were not required to measure accounting profit using tax rules, but omits any reference to the 1990s requirement that requires that the taxable profits of all entities should be based on their accounting profits (which makes the U.K. similar to Belgium and Sweden and may have affected whether entities elect to use IFRS instead of U.K. accounting standards in their legal-entity financial statements).

Germany is often referred to as a country in which there are strong links between accounting and taxation. Wolfgang Ballwieser explains how that link has now weakened because purely tax-driven values are no longer allowed in commercial accounts. German entities now have to follow three different systems: IFRS in their consolidated financial statements; German GAAP in their legal-entity financial statements; and tax rules for the determination of the tax liability.

This use of different accounting policies in consolidated and legal-entity financial statements is a French idea, which is what Claude Bocqueraz describes as the duality of French accounting. It has not only spread to Germany, but it has also made possible the approach in the IAS regulation, which requires the use of IFRS in the consolidated financial statements of a publicly traded entity but allows the use of national standards in the parent's legal-entity financial statements.

While all of the essays deal extensively with the different historical influences on accounting and financial reporting, only a few show how this has affected the technical accounting and financial reporting requirements. One exception to the general rule is Ballwieser's essay, which provides an insight into the underlying concept in German accounting of creditor-oriented prudent determination of profit, which is mandatory for all business entities. Another exception is Kees Camfferman's essay that explains the links between Dutch accounting and the concept of business economics (*bedrijfseconomie*) and the resulting emergence, use, and eventual demise of current cost accounting. Beyond these two examples, there is little about the technical aspects of accounting and financial reporting beyond passing mentions of hidden or secret reserves, the historical cost model, and a few other issues.

Technical issues aside, there is a wealth of material in the essays that will help researchers understand how accounting, financial reporting, and public policy in ten European countries have developed. In addition to the issues referred to earlier in this review, the country essays deal with the creation of independent private standard-setting bodies, the need for an audit, and the growth of the accounting and auditing professions. The essays on Belgium, Germany, The Netherlands, Switzerland, and the United Kingdom also address the roles of academics and practitioners who have contributed to accounting thought.

I recommend this collection of essays to anybody who wants to understand how national accounting in Europe has developed. Such an understanding will lead to a greater appreciation of the attitudes within Europe to the convergence of accounting standards. For post-graduate courses that continue to explore the history of accounting in individual countries, this volume will be an invaluable source of information. For researchers, the volume should help identify a glut of issues that warrant further study.

EDITORIAL POLICY AND STYLE INFORMATION

EDITORIAL POLICY

According to the policies set by the Publications Committee (which were endorsed by the Executive Committee and were published in the *Accounting Education News*, June 1987), *The Accounting Review* "should be viewed as the premier journal for publishing articles reporting the results of accounting research and explaining and illustrating related research methodology. The scope of acceptable articles should embrace any research methodology and any accounting-related subject, as long as the articles meet the standards established for publication in the journal ... No special sections should be necessary. The primary, but not exclusive, audience should be—as it is now—academicians, graduate students, and others interested in accounting research."

The primary criterion for publication in *The Accounting Review* is the significance of the contribution an article makes to the literature. Topical areas of interest to the journal include accounting information systems, auditing and assurance services, financial accounting, management accounting, taxation, and all other areas of accounting, broadly defined. The journal is also open to all rigorous research methods.

The efficiency and effectiveness of the editorial review process is critically dependent upon the actions of both authors submitting papers and the reviewers. Authors accept the responsibility of preparing research papers at a level suitable for evaluation by independent reviewers. Such preparation, therefore, should include subjecting the manuscript to critique by colleagues and others and revising it accordingly prior to submission. The review process is not to be used as a means of obtaining feedback at early stages of developing the research.

Reviewers and editors are responsible for providing constructive and prompt evaluations of submitted research papers based on the significance of their contribution and on the rigor of analysis and presentation.

MANUSCRIPT PREPARATION AND STYLE

The Accounting Review's manuscript preparation guidelines follow *The Chicago Manual of Style* (15th ed.; University of Chicago Press). Another helpful guide to usage and style is *The Elements of Style*, by William Strunk, Jr., and E. B. White (Macmillan). Spelling follows *Webster's Collegiate Dictionary*.

Format

1. All manuscripts should be formatted in 12-point font on 8 1/2 × 11″ paper and should be double-spaced, except for indented quotations.
2. Manuscripts should be as concise as the subject and research method permit, generally not to exceed 7,000 words.
3. Margins should be at least one inch from top, bottom, and sides.
4. To promote anonymous review, authors should not identify themselves directly or indirectly in their papers or in experimental test instruments included with the submission. Single authors should not use the editorial "we".
5. A cover page should show the title of the paper, all authors' names, titles and affiliations, email addresses, and any acknowledgments.
6. The American Accounting Association encourages use of gender-neutral language in its publications.
7. Experimental studies using human subjects should contain a footnote affirming that approval has been granted by the institution where the experiment took place.
8. Headings should be arranged so that major headings are centered, bold, and capitalized. Second-level headings should be flush left, bold, and both uppercase and lowercase. Third-level headings should be flush left, bold, italic, and both uppercase and lowercase. Fourth-level headings should be paragraph indent, bold, and lowercase. Headings and subheadings should not be numbered. For example:

A CENTERED, BOLD, ALL CAPITALIZED, FIRST-LEVEL HEADING

A Flush Left, Bold, Uppercase and Lowercase, Second-Level Heading

A Flush Left, Bold, Italic, Uppercase and Lowercase, Third-Level Heading

A paragraph indent, bold, lowercase, fourth-level heading. Text starts . . .

Pagination: All pages, including tables, appendices and references, should be serially numbered. Major sections should be numbered in Roman numerals. Subsections should not be numbered.
Numbers: Spell out numbers from one to ten, except when used in tables and lists, and when used with mathematical, statistical, scientific, or technical units and quantities, such as distances, weights and measures. For example: three days; 3 kilometers; 30 years. All other numbers are expressed numerically.

Percentages and Decimal Fractions: In nontechnical copy use the word percent in the text; in tables and figures, the symbol % is used.

Hyphens: Use a hyphen to join unit modifiers or to clarify usage. For example: a cross-sectional equation; re-form. See *Webster's* for correct usage.

Keywords: The abstract must be followed by at least three keywords to assist in indexing the paper and identifying qualified reviewers.

Abstract/Introduction

An Abstract of about 100 words (150 maximum) should be presented on a separate page immediately preceeding the text. The Abstract should concisely inform the reader of the manuscript's topic, its methods, and its findings. The Keywords statement should appear immediately below the Abstract. The text of the paper should start with a section labeled "I. Introduction," which provides more details about the paper's purpose, motivation, methodology, and findings. Both the Abstract and the Introduction should be relatively nontechnical, yet clear enough for an informed reader to understand the manuscript's contribution. The manuscript's title, but neither the author's name nor other identification designations, should appear on the Abstract page.

Tables and Figures

The author should note the following general requirements:

1. Each table and figure (graphic) should appear on a separate page and should be placed at the end of the text. Each should bear an Arabic number and a complete title indicating the exact contents of the table or figure. Tables and figures should define each variable. The titles and definitions should be sufficiently detailed to enable the reader to interpret the tables and figures without reference to the text.
2. A reference to each graphic should be made in the text.
3. The author should indicate where each graphic should be inserted in the text.
4. Graphics should be reasonably interpreted without reference to the text.
5. Source lines and notes should be included as necessary.
6. When information is not available, use "NA" capitalized with no slash between.
7. Figures must be prepared in a form suitable for printing.

Equations: Equations should be numbered in parentheses flush with the right-hand margin.

DOCUMENTATION

Citations: Within-text citations are made using an author-year format. Cited works must correspond to the list of works listed in the "References" section. Authors should make an effort to include the relevant page numbers in the within-text citations.

1. In the text, works are cited as follows: author's last name and year, without comma, in parentheses. For example: one author, (Berry 2003); two authors, (Fehr and Schmidt 2003); three or more authors, (Dechow et al. 1998); more than one work cited, (Cole and Yakushiji 1984; Dechow et al. 1995; Levitt 1998); with two works by the same author(s), (Nelson 2003, 2005).
2. Unless confusion would result, do not use "p." or "pp." before page numbers. For example, (Dechow and Dichev 2002, 41–42).
3. When the reference list contains two or more works by the same author (as the only author or first of two or more authors) published in the same year, the suffix a, b, etc., is appended to the date in the within-text citations and in the "References" section. For example, (Johansson 2004a, 2004b, 2004c; Baiman and Rajan 2002a, 2002b; Dhaliwal et al. 2005a, 2005b).

4. When the author's name is mentioned in the text, it need not be repeated in the citation. For example: "Cohen et al. (2005) provide ..."
5. Citations to institutional works should use acronyms or short titles where practicable. For example: (NCFFR, The Treadway Commission 1987).
6. If the paper refers to statutes, legal treatises, or court cases, citations acceptable in law reviews should be used.

Reference List: Every manuscript must include a "References" section that contains only those works cited within the text. Each entry should contain all information necessary for unambiguous identification of the published work. Use the following formats (which follow *The Chicago Manual of Style*):

1. Arrange citations in alphabetical order according to the surname of the first author or the name of the institution or body responsible for the published work.
2. Use authors' initials instead of proper names.
3. For two or more authors, separate authors with a comma, including a comma before "and" (Dechow, P. M., R. Sloan, and A. Sweeney).
4. Date of publication follows the author's (authors') name(s).
5. Titles of journals or newspapers should not be abbreviated.

Sample entries are as follows:

Baiman, S., and M. Rajan. 2002a. The role of information and opportunism in the choice of buyer-supplier relationships. *Journal of Accounting Research* 40 (2): 247–278.

Footnotes: Footnotes are not used for documentation. Textual footnotes should be used only for extensions and useful excursions of information that if included in the body of the text might disrupt its continuity. Footnotes should be inserted using the "footnote" or "endnote" feature of the word processing software which will automatically number the footnotes throughout the manuscript with superscript Arabic numerals.

SUBMISSION OF MANUSCRIPTS

Authors should note the following guidelines for submitting manuscripts:

1. Manuscripts currently under consideration by another journal or publisher should not be submitted. The author must state upon submission that the work is not submitted or published elsewhere.
2. For manuscripts reporting on field surveys or experiments: If the additional documentation (e.g., questionnaire, case, interview schedule) is sent as a separate file, then all information that might identify the author(s) must be deleted from the instrument.
3. New manuscripts must be submitted through the Manuscript Submission and Peer Review System, located at http://accr.allentrack.net. The site contains detailed instructions regarding the preparation of files for submission. Revisions of manuscripts originally submitted before June 1, 2011 should be sent via email to the senior editor, John Harry Evans III, at tar@katz.pitt.edu. Please submit separate files for (1) the manuscript's title page with identifying information (not forwarded to reviewers), (2) the manuscript with title page and all other identifying information removed, and (3) any necessary supplemental files, such as experimental instructions and/or response memoranda on invited revisions.
4. A nonrefundable submission fee is required unless explicitly waived by the editor for invited revisions of previous submissions. The submission fee in U.S. funds is $200.00 for members and $400.00 for nonmembers of the AAA payable by credit card (VISA or MasterCard only). The payment form is available online at: https://aaahq.org/AAAforms/journals/tarsubmit.cfm. If you are unable to pay by credit card or have any questions, please contact the AAA Member Services Team at (941) 921-7747 or info@aaahq.org.
5. Revisions must be submitted within 12 months from the decision letter inviting a revision.

COMMENTS

The Accounting Review welcomes submissions of comments on previous *TAR* articles. Comments on articles previously published in *The Accounting Review* will generally be reviewed by two reviewers, usually including an author of the original article (to assist the editor in evaluating whether the submitted comment represents the prior article accurately) and an additional reviewer who is independent of the original article. If a comment is accepted for publication, the original author will generally be invited to reply. All other editorial requirements, as enumerated above, apply to proposed comments.

POLICY ON REPRODUCTION

An objective of *The Accounting Review* is to promote the wide dissemination of the results of systematic scholarly inquiries into the broad field of accounting.

Permission is hereby granted to reproduce any of the contents of the *Review* for use in courses of instruction, as long as the source and American Accounting Association copyright are indicated in any such reproductions.

Written application must be made to the American Accounting Association, 5717 Bessie Drive, Sarasota, FL 34233-2399, for permission to reproduce any of the contents of the *Review* for use in other than courses of instruction—e.g., inclusion in books of readings or in any other publications intended for general distribution. In consideration for the grant of permission by the *Review* in such instances, the applicant must notify the author(s) in writing of the intended use to be made of each reproduction.

Except where otherwise noted in articles, the copyright interest has been transferred to the American Accounting Association. Where the author(s) has (have) not transferred the copyright to the Association, applicants must seek permission to reproduce (for all purposes) directly from the author(s).

POLICY ON DATA AVAILABILITY

The AAA's Executive Committee policy (originally adopted in 1989, and amended in 2009) is that the objective of the Association-wide journals (*The Accounting Review, Accounting Horizons, Issues in Accounting Education*) is to provide the widest possible dissemination of knowledge based on systematic scholarly inquiries into accounting as a field of professional research, and educational activity. To fulfill this objective, authors are encouraged to make their data available for use by others in extending or replicating results reported in their articles.

JULY 2012 PLACEMENT ADS

The deadline for free position ads to be included in this section of *The Accounting Review* is two months prior to the desired publication in the January, March, May, July, September, or November issues. Position ads, which are free with the purchase of a job posting in the AAA Career Center, should provide all relevant information about the available positions and must include contact information or application instructions for interested candidates. For more information on how to purchase a job posting in the Career Center, or for up-to-date, detailed information about the placement listings in this issue, please go to the AAA website at http://aaahq.org and click on "Career Center," or call our office at 941-921-7747.

WEBER STATE UNIVERSITY is seeking an individual to teach in the areas of tax or auditing; execute scholarship in field; provide service to university, community, and profession. Minimum Qualifications: ABD in accounting with expectation of completion of Ph.D. or D.B.A. within one year required. Area of emphasis in either tax or audit. Degree must be from a regionally accredited institution. Provide evidence of teaching effectiveness. To apply, complete the online application at: faculty/staff data form at http://jobs.weber.edu; attach a letter of application that addresses your qualifications for teaching tax and/or audit, a *cv*, and the names and contact information for three references. Screening is ongoing and will continue until position is filled. Criminal background check required as a condition of employment. For information, contact: hr@weber.edu; or (801) 626-6032. WSU is an AA/EO Employer.

VIRGINIA POLYTECHNIC INSTITUTE & STATE UNIVERSITY, Pamplin College of Business, Department of Accounting & Information Systems seeks to fill one or two tenure-track or visiting positions to begin August 10, 2012. Preference will be given to qualified candidates at the Assistant or Associate Professor levels. Individuals with teaching and research interests in the area of auditing, financial, or managerial accounting are preferred, but other areas will also be considered. Successful candidates will have a Ph.D. in accounting from an AACSB-accredited school, a program of scholarly research consistent with the rank applied for, and instructional capabilities at both the undergraduate and graduate levels. Information about the department and its programs is available at: http://www.acis.pamplin.vt.edu. Interested candidates *must* apply online at: http://www.jobs.vt.edu (posting number 0121558) and include with the electronic application a cover letter, resume, and three letters of recommendation, or names and contact information of three references. Review of applications will begin March 15, 2012. General inquiries should be directed to: Professor Greg Jenkins, Chair of the Recruiting Committee (Email: greg.jenkins@vt.edu) or Professor Reza Barkhi, Department Head, 3007 Pamplin Hall (0101), Blacksburg, VA 24061. Virginia Tech is an Equal Opportunity/Affirmative Action Employer.

WESTERN KENTUCKY UNIVERSITY invites applications from professionally qualified candidates for an Executive-in-Residence nine-month, non-tenure-track faculty position in the Department of Accounting. Qualifications include Master's in Accounting or M.B.A. from an AACSB-accredited university, CPA, minimum of five years of professional experience, and strong communication and technical skills. The superior candidate would have prior teaching experience in the field as well as the ability and willingness to teach upper-level courses in areas such as financial, auditing, or systems. The candidate must be committed to preparing students for success in multicultural business environments. The normal teaching load is 12 hours per semester. Please mail copies of application letter, resume, transcripts, and three letters of reference as soon as possible to: Accounting Search Committee, Western Kentucky University, 1906 College Heights Blvd #11061, Bowling Green, KY 42101. Additional information is available at: http://www.wku.edu/employment/faculty.php. Western is an Affirmative Action/Equal Opportunity Employer.

UNIVERSIDAD DEL TURABO, Sistema Universitario Ana G. Mendez, School of Business and Entrepreneurship (Puerto Rico) is seeking an Assistant Professor to teach Accounting and Finance courses. The ideal candidate must have a Ph.D. or D.B.A. in Accounting, or in a closely related field and be a Certified Public Accountant (CPA) with area of research in accounting. Candidates should be committed to do scholarly research. Candidates should have a proven track record of scholarly publications. Experience in teaching at the university level is preferred. Must have excellent communication skills in English and Spanish (verbal and written). If you are qualified and interested, please send your confidential resume and salary history to: Mrs. Camile Pérez, Recruitment Director at: camperez@suagm.edu

UNIVERSITY OF PITTSBURGH, Joseph M. Katz Graduate School of Business seeks to further strengthen its capability in and commitment to leadership and ethics in business, recognizing that ethics without leadership is ineffective and leadership without ethics can be misguided. Our goal is to advance teaching and research in leadership and ethics and promote interactions with both business and the non-profit sector. Our commitment to these goals is evidenced and supported by our David Berg Center for Leadership and Ethics, which plays a powerful role in focusing faculty research and teaching efforts and building relationships with business and non-profit organizations. To enrich our research, teaching, and outreach programs in leadership and ethics, we invite nominations and applications for the H. J. Zoffer Chair in Leadership and Ethics. This newly created chair, honoring Dean Emeritus H. J. Zoffer, is available beginning in September 2012. The successful candidate will be a recognized scholar with a proven teaching and research record in the area of leadership and ethics. The candidate must have the capacity to work effectively with faculty across business disciplines, motivate students at all levels—undergraduate, M.B.A., and Ph.D.—and engage the business community. Applications, nominations, or inquiries should be sent to: Dr. John C. Camillus, H. J. Zoffer Chair Search Committee, University of Pittsburgh, Mervis Hall, Pittsburgh, PA 15260; Email: camillus@katz.pitt.edu. The University of Pittsburgh is an Affirmative Action/Equal Opportunity Employer. Women and members of minority groups under-represented in academia are especially encouraged to apply.

DELAWARE STATE UNIVERSITY, College of Business Accounting invites applications for Adjunct positions for a Visiting Assistant/Associate Professor, starting Fall 2013, in The People's Republic of China. Qualified applicants will teach in China for a 14-week session. We are recruiting for positions in Introductory Accounting, Accounting Information Systems (AIS), Intermediate, and Cost Accounting. The successful candidate should have a doctorate in accounting from an accredited institution. ABD in Accounting or M.B.A./CPA will be considered. The successful candidates must be an academically qualified or professionally qualified faculty member and an effective teacher. Courses will be taught in English. Compensation is competitive. The College of Business is accredited by AACSB International and is housed in a high-tech teaching facility and serves approximately 20 percent of the University's total population of 4,000+ and offers Bachelor and M.B.A. degrees. A review of applications will begin immediately and continue until vacancies are filled. Post a letter of application and *vitae* on the university's website at: http://www.desu.edu, Administration/Human Resources/Job Openings, or go to: http://tbe.taleo.net/NA12/ats/careers/jobSearch.jsp?org=DESU&cws=1, and scroll down to end of page to apply. For inquiries, please contact: Dr. Bernadette Ruf, Chair of Accounting, Economics and Finance, College of Business, Delaware State University, 1200 N. DuPont Highway, Dover, DE 19901-2277; Email: bruf@desu.edu.

FAIRFIELD UNIVERSITY, Accounting Department invites applications for a tenure-track position at the Assistant or Associate Professor level in the Charles F. Dolan School of Business to begin Fall 2013. Qualified individuals in all specialty areas of accounting will be considered; preference will be given to those with an ability to teach in multiple areas. Candidates must have or be near completion of a doctoral degree. Professional certification in accounting is preferred. Candidates will be expected to demonstrate a strong commitment to excellence in teaching, scholarly research, and service to the Department and University. Fairfield University is Connecticut's Jesuit comprehensive university located on a scenic suburban campus near Long Island Sound, about one hour outside New York City. The Charles F. Dolan School of Business is AACSB-accredited and was recently named a "top 15" accounting program by the *Princeton Review*'s "Student Opinion Honors for Business Schools." A review of candidates will begin immediately and continue until the position is filled or September 30, 2012, whichever occurs first. Please send a letter of application, *curriculum vitae*, transcripts, and three references to: Dr. Joan Van Hise, Chair, Accounting Department, Charles F. Dolan School of Business, Fairfield University, Fairfield, CT 06824; Email: jvanhise@fairfield.edu. Fairfield University is an Equal Opportunity Employer. Women, minorities, veterans, and persons with disabilities are encouraged to apply. Visit our website at: http://www.fairfield.edu.

MORGAN STATE UNIVERSITY, Department of Accounting and Finance, Graves School of Business and Management invites applications for a tenure-track position starting in January or August 2013 at the rank of Assistant or Associate Professor. All areas in accounting will be considered. Candidates should have a Ph.D. degree in accounting from an AACSB-accredited institution. The preference will be given to those candidates who have a research record in accounting and demonstrate a commitment to high-quality teaching at both the undergraduate and graduate levels. The University has business school accreditation and accounting accreditation by the AACSB. The business school offers a B.S. degree in accounting and a Ph.D. degree in Business Administration with an accounting concentration. Master's level accounting courses are offered in the general M.B.A. program. A master's degree program in accounting will be offered starting in the Fall 2012. Morgan State University is located in Baltimore, Maryland, adjacent to the Chesapeake Bay and famous for its tourist attraction, The Inner Harbor. Baltimore is 48 miles from the District of Columbia and only a short driving distance from other major cities such as Philadelphia and New York City. Interested candidates should send academic *vitae* to: Alex P. Tang, Chair, Recruiting Committee, Department of Accounting & Finance, Morgan State University, Baltimore, MD 21251; Email: Alex.Tang@morgan.edu. We will be interviewing at the 2012 AAA Annual Meeting. Morgan State University is an affirmative action-equal opportunity employer.

PEKING UNIVERSITY, HSBC Business seeks applicants for Assistant/Associate/Full Professor levels in Management, Marketing, and Accounting. Job Responsibility: Quality research and teaching. The College: Peking University HSBC Business School is located in the thriving entrepreneurial city of Shenzhen and adjacent to the financial hub of Hong Kong. The University: Peking University is among the most prestigious education institutes in China. Qualifications: A successful applicant should hold a Ph.D. or is expected to receive one before July 2013. Senior applicants should have excellent records on research and teaching. To apply, please submit your application package to: hr_faculty@phbs.pku.edu.cn. Your package should include a cover letter, a *curriculum vita*, a research paper, three reference letters, and evidences of effective teaching.

INDIANA UNIVERSITY SOUTHEAST, School of Business is currently seeking applicants for a tenure-track appointment beginning in Fall 2013 for a Ph.D. in Accounting. Candidate will teach auditing and financial reporting. Ph.D. in accountancy required. CPA/CMA is desirable. Professional work experience preferred. Applications will be accepted until the position is filled, review to begin July 1, 2012. Starting date is August 1, 2013. Applicants should send *vita*, three letters of recommendation, and transcript to: hr@ius.edu, Attention: Tenure Track in Accounting-Search and Screen Committee. For additional information about the position, call Professor Doug Barney, Chair Search and Screen Committee (812) 941-2532. Indiana University Southeast is one of eight campuses in the Indiana University system. We are dedicated to providing high-quality education and lifetime growth opportunities for the people of Southern Indiana and the Greater Louisville region. Currently more than 7,000 students are enrolled in six master's degree programs (including two in the School of Business) and 38 bachelor's degree programs. Our campus facilities are located on a beautiful 177-acre tract at the foot of the "knobs" area of Southern Indiana, only ten minutes from downtown Louisville, KY. The campus has experienced significant growth as evidenced by construction of a new state-of-the-art library and five student residence halls. For more information on our campus and the School of Business please visit: http://www.ius.edu. We will be attending the 2012 American Accounting Association meeting in Washington, D.C. Indiana University is committed to a learning environment that actively seeks to support students, faculty, and staff from diverse backgrounds. Consistent with the University's commitment to diversity, persons from traditionally under-represented groups are strongly encouraged to apply. If you require reasonable accommodations due to a disability, please contact Human Resources. Indiana University Southeast is an Affirmative Action/Equal Opportunity Employer.

UNIVERSITY OF PENNSYLVANIA, Wharton School, Accounting Department is seeking applicants for a full-time, tenure-track faculty position at any level: Assistant, Associate, or Full Professor, in Financial, Managerial, and Tax Accounting. Demonstrated ability or potential for high-quality research and teaching are important. Applicants must have a Ph.D. (expected completion by June 30, 2014 is acceptable) from an accredited institution and have an outstanding research record or potential. The appointment is expected to begin July 1, 2013. Applications, including cover letter, *curriculum vitae*, and recent publications or working papers, must be submitted via our secure website: http://accounting.wharton.upenn.edu/. Junior-level candidates should also include contact information for up to three references who will be asked to submit letters of recommendation. The deadline for applications is November 30, 2012. Contact: Professor Brian Bushee, Accounting Department, The Wharton School, University of Pennsylvania, 1300 Steinberg-Dietrich Hall, Philadelphia, PA 19104-6365. The University of Pennsylvania values diversity and seeks talented students, faculty and staff from diverse backgrounds. The University of Pennsylvania is an Equal Opportunity/Affirmative Action Employer. Women, minority candidates, veterans, and individuals with disabilities are strongly encouraged to apply.

CENTRAL MICHIGAN UNIVERSITY, College of Business Administration, invites application for Chair for the School of Accounting beginning Fall 2012. The candidate should have an earned doctorate in Accounting, have a strong record of teaching and research commensurate with rank of Associate or Full Professor. The Chair will work with the School's administration to support and increase the intellectual contributions of the faculty and to expand academic programs. The Chair will provide oversight to undergraduate accounting majors; collaborate with faculty members and administrators to articulate program aspirations, initiatives, and policies; and will represent these programs to stakeholders inside and outside the University community. Compensation will be competitive and commensurate with qualifications and experience and includes a generous benefit package. The documents that applicants should submit are listed at Central Michigan University Jobs website: http://www.jobs.cmich.edu. CMU, an AA/EO institution, strongly and actively strives to increase diversity within its community (see http://www.cmich.edu/aaeo/).

SOUTHERN METHODIST UNIVERSITY, Cox School of Business, Tenure-Track Faculty Position in Accounting (#049944) for Fall 2013. Hiring is contingent upon a satisfactory background check. Applicants must have a Ph.D. (or equivalent) in Accounting from an accredited institution or will complete a Ph.D. by August 1, 2013, and have an interest in research and teaching in financial, managerial, or tax accounting. Candidates should be qualified to teach at the undergraduate or graduate level. Salary and teaching loads are competitive, based on qualifications and experience. Applicants should send *curriculum vitae*, published/working papers, three letters of reference and evidence of teaching effectiveness to: Accounting Recruiting Committee, Southern Methodist University, Cox School of Business, PO Box 750333, Dallas, TX 75275-0333; Email: ACCT-RECRUIT@mail.cox.smu.edu. Applications must be received by January 15, 2013, but will be accepted until the position is filled. SMU is an Affirmation Action/Equal Opportunity/Title IX Employer.

UNIVERSITY OF NEBRASKA–LINCOLN, School of Accountancy invites applications for a tenured appointment beginning August 2013. Nebraska is committed to establishing a research presence and productivity consistent with our entry into the Big Ten Conference and the Committee on Institutional Cooperation, the academic affiliation of the Conference. The successful candidate will hold the newly endowed Lienemann Chair in Accounting and will be a Full Professor. Candidates are required to hold a Ph.D. degree in accounting or related area from an AACSB-accredited College of Business and must have an established record of publication in A-level accounting and/or finance journals. All areas of teaching and research interest will be considered; we are particularly interested in individuals who are strong organizational citizens and interested in being active members of a rich academic community. Salary, benefits, and research support are very competitive and consistent with other Big Ten Universities. The College of Business Administration is under the leadership of Dean Donde Plowman and Associate Deans Kathy Farrell and Ravi Sohi; the research, teaching, and engagement missions of the College have been significantly refocused to align with the university's entrance into the Big Ten. *BusinessWeek* ranked UNL's M.B.A. program 4th in the country among part-time M.B.A. programs. The college continues to build on and further develop its research strength. Increased support for research and close proximity to thriving business communities of Omaha and Lincoln help advance the college's research goals. The college prides itself in being an open and collaborative community. Initial screening of applicants will begin July 1, 2012 and continue until the position is filled. To be considered for the position, go to http://employment.unl.edu, requisition 120368, and complete the Faculty/Academic Administrative Form. In addition, candidates need to send a letter of interest, *curriculum vitae*, a sample of publications and current research, evidence of teaching experience and ability, and contact information for at least three references to: Dr. David Smith, School of Accountancy, 387 CBA, 512 N 12th St., PO Box 880488, Lincoln, NE 68588-0488; Email: dsmith19@unl.edu. The University of Nebraska has an active National Science Foundation ADVANCE gender equity program, and is committed to a pluralistic campus community through affirmative action, equal opportunity, work-life balance, and dual careers. We assure reasonable accommodation under the ADA; contact Dr. Paul Shoemaker at (402) 472-2337 for assistance.

LONGWOOD UNIVERSITY, Department of Accounting, Economics, Finance and Real Estate, College of Business and Economics is seeking qualified applicants for a tenure-track position in Accounting to begin August 2013. For more information and to apply please visit: http://www.longwood.edu/hr/jobs.htm. Review of applications will begin immediately. Applicants should send a letter of application and *vita to* (indicate position #F0193). If additional information is needed, contact Dr. Bennie Waller at: wallerbd@longwood.edu.

UNIVERSITY OF MINNESOTA–DULUTH, Department of Accounting, Labovitz School of Business and Economics has a full-time, nine-month, tenure-track Instructor/Assistant Professor/Associate Professor position in Accounting, available beginning Fall 2013. Job duties and responsibilities include teaching, research, and service. Essential qualifications include: Applicants must be ABD (with a clear plan for completion by December 31, 2013) from a doctoral program in Accounting, or Business Administration with a concentration in Accounting, from an AACSB-International-accredited school or major internationally recognized university (no more than 25 percent of the credits for the degree can be online). If the candidate is ABD for more than two years, there must be evidence of, at minimum, manuscript submissions to a refereed accounting-related journal. Evidence of potential for scholarship is essential, as is the demonstrated commitment to developing a research agenda in accounting. Demonstrated teaching experience (graduate assistant or corporate training experience acceptable). Demonstrated written communication skills appropriate to a faculty position are also essential. The University of Minnesota requires that you apply online for this position. For a complete position description and information on how to apply online, visit: http://employment.umn.edu/, and search for Job Requisition 177885. Complete applications will be reviewed beginning September 10, 2012. The University of Minnesota is an Equal Opportunity Educator and Employer.

THE UNIVERSITY OF OKLAHOMA, John T. Steed School of Accounting anticipates one visiting faculty opening for the Fall 2012 and Spring 2013 semesters. Rank: Visiting Assistant or Associate Professor. Education: Ph.D. in accounting or Master's degree and CPA or other professional qualifications (CMA, CIA, etc.). Will consider candidates not holding a Master's degree who are CPAs with teaching experience. Teaching: Candidates must be able and willing to teach at both the undergraduate and graduate level. Candidates must possess some prior teaching experience and provide evidence of quality teaching performance. Evaluation: Qualified candidates will be evaluated based on evidence of quality teaching and fit to departmental teaching needs. Salary and fringe benefits: Open and competitive based on applicable experience. Anticipated appointment date: August 15, 2012–May 15, 2013. General: Qualified individuals are encouraged to submit a resume and evidence of teaching qualifications to: Jan Nelson, Managerial Associate, Steed School of Accounting, Price College of Business, The University of Oklahoma, 307 W. Brooks, AH 200, Norman, Oklahoma 73019-4004; Email: jnelson@ou.edu; Fax: (405) 325-7348. For questions, contact the Director of the Steed School of Accounting, Dr. Fran Ayres at: fayres@ou.edu. Interested applicants may also apply for the open Assistant Faculty position in the Steed School of Accounting. The screening of applications will begin immediately. Applications will be accepted until the position is filled. The University of Oklahoma is an Equal Opportunity/Affirmative Action Employer. Women and minorities are encouraged to apply.

UNIVERSITY OF MASSACHUSETTS LOWELL, AACSB-accredited Manning School of Business (MSB) invites applications for multiple tenure-track positions in Accounting at the rank of Full/Associate/Assistant Professor. A new M.S.A. program will launch in September 2012. In addition, the MSB expects to add a new Accounting track to its recently approved Ph.D. in Business Administration, and to occupy a new state-of-the-art instructional facility, within the next three years. The MSB serves more than 2,000 undergrad and M.B.A. students in classrooms and online. The University offers nearly 15,000 students more than 120 degrees and academic opportunities, including internships, co-op programs, and study-abroad programs. Requirements: An earned Ph.D. or D.B.A. in Accounting or a related discipline by the starting date (September 2013 or later). A demonstrated record of, or at the Assistant level a strong potential for, high-quality research. A demonstrated record of high-quality grad/undergrad instruction in some combination of Financial/Managerial Accounting, AIS, Auditing, or Taxes. Excellent interpersonal skills and the ability to speak and write English clearly. The ability to work with a diverse student and faculty population. Strong consideration given to candidates with public accounting or corporate experience, preferably with CPA, CMA, etc. Apply online at: http://jobs.uml.edu. Attach (1) a statement of professional interests and goals, (2) *cv*, (3) samples of research work, and (4) teaching philosophy and evidence of teaching effectiveness. Applications will be accepted until the posting is closed. Contact the University of Massachusetts Lowell Human Resources Department at (978) 934-3560 for information regarding benefits and related employment matters.

CALIFORNIA POLYTECHNIC STATE UNIVERSITY, SAN LUIS OBISPO, Orfalea College of Business (OCOB) seeks candidates for the Executive Director position for the Center of Excellence in Accounting. The Executive Director, under the direction of the OCOB Dean, will lead the development of the Accounting Center to enhance relationships with external stakeholders, students, and faculty, as well as serve as an instructor for undergraduate and graduate service learning programs in taxation. An important aspect of the position will be to cultivate, solicit, and steward donors and prospective donors to support and sustain the vision, development, and short- and long-term goals and objectives for the Accounting Center and its faculty and programs. Candidates must have minimum of five years of professional practice as a CPA or attorney at law. Preferred qualifications include grant and proposal writing experience and/or a Master's degree. To apply, visit: http://www.calpolyjobs.org, complete a required online application, and submit to requisition #102497. Please see online instructions regarding attaching supplemental documents. Review begin date is May 30, 2012 and will remain open until filled. Cal Poly is strongly committed to achieving excellence through cultural diversity. The University actively encourages applications and nominations of all qualified individuals. EEO.

PACE UNIVERSITY, Lubin School of Business invites applications for a full-time, tenure-track position in financial accounting, at the Assistant or Associate level, starting Fall 2013. A successful candidate for this position must reflect the School's commitment to excellence in teaching and scholarly research. A Ph.D. is required and practical experience is beneficial. The Lubin School of Business of Pace University is a recognized leader in business education and is committed to preparing professionals for successful careers in the global economy. The School offers an extensive array of undergraduate, graduate, and post-graduate programs on campuses in New York City and Westchester County. The Accounting Department is fully accredited by the AACSB-International Association for Management Education. Salary and benefit package is competitive. Please email your resume to: Dr. Rudy Jacob at: rjacob@pace.edu. Pace University is an Affirmative Action/ Equal Opportunity Employer.

UNIVERSITY OF WISCONSIN–WHITEWATER, College of Business and Economics, Accounting Department invites applications for multiple full-time, tenure-track Assistant Professor positions in the areas of Tax, Financial, and Managerial Accounting beginning Fall 2013. Applicants should have a doctoral degree in Accounting; however, applicants with doctoral degrees in closely related fields and ABDs will be considered. The College of Business and Economics is AACSB-accredited so applicants must be academically qualified under those standards. Preference will be given to applicants with CPA certification and accounting practical experience. The UWW Accounting Department strives to be among the best regional public comprehensive university accounting departments by focusing on quality teaching, a solid research portfolio, and service. The complete position announcement is at: http://www.uww.edu/employment/unclassified.html. For more information about our department go to: http://www.uww.edu/cobe/accounting. To apply, send a letter of application, resume, contact information for three references, and evidence of teaching effectiveness. Original transcripts will be required for finalists. Application materials should be emailed to Joanna Stradinger at: stradinj@uww.edu or mailed to: Dr. Carol J. Normand, Search and Screen Committee Chair, Attn: Joanna Stradinger, Accounting Department, University of Wisconsin–Whitewater, 800 W. Main Street, Whitewater, WI 53190-1790. Only complete applications will be considered. Apply by July 27, 2012 to be considered for an interview at the AAA Annual Meeting in Washington, D.C., August 4–8. Applications received by October 1, 2012 are ensured consideration. Positions will remain open until filled. UW–Whitewater is an Equal Opportunity/ Affirmative Action Employer.

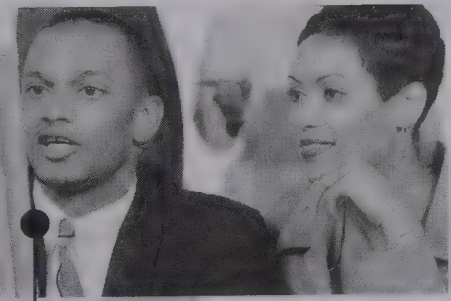
Why use ProQuest business resources from your library?

Your library and ProQuest—providing the best business information available

Whether you are a student writing a paper, an instructor recommending classroom support, an entrepreneur contemplating a new venture, or a job seeker researching regional market conditions, you'll be prepared with the resources you need—from ProQuest.

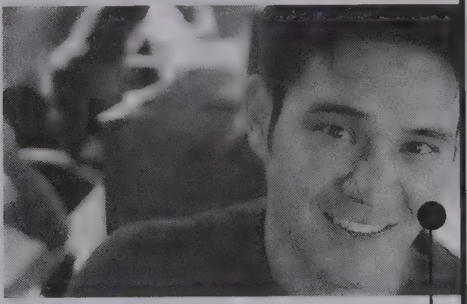
Databases like **ProQuest Accounting & Tax, ABI/INFORM** and **ProQuest Entrepreneurship** feature everything from e-books and annual reports, to education tools and market research reports. And tools like RSS feeds and email alerts keep the search going even when you're not at the computer. All of that is available from your library, via remote access, putting you on the path to discovery, anywhere, anytime.

Get free and instant access to hundreds of online databases!
Sure, you can use the open web for research, but when you're looking for authoritative and reliable content, online databases from ProQuest via your local library are your best starting point. Visit your library's website to learn more.



"While I'm in school, I'm also looking for work."

"Even from home, I can log on to get the information I need from renowned databases from ProQuest ... all it takes is a library card!"



"As a small business owner, I'm always seeking resources to help guide my plans."

Board of Directors

President	Karen V. Pincus, University of Arkansas
President-Elect	Mary E. Barth, Stanford University
Past President	Gregory B. Waymire, Emory University
Vice President–Finance	Dale L. Flesher, The University of Mississippi
Vice President–Research and Publications	Steven J. Kachelmeier, The University of Texas at Austin
Vice President–Education	Alan Reinstein, Wayne State University
Director–Focusing on Membership	David E. Stout, Youngstown State University
Director–Focusing on International	Recep Pekdemir, Istanbul University
Director–Focusing on Professional Relations	Ken Bouyer, Ernst & Young LLP
Director–Focusing on Intellectual Property	Christine A. Botosan, The University of Utah
Director–Focusing on Segments	Anne L. Christensen, Montana State University

The Executive Director of the Association is Tracey E. Sutherland.

The American Accounting Association was founded in 1916 as the American Association of University Instructors in Accounting. Its present name was adopted in 1936. The Association is a voluntary organization of persons interested in accounting education, research, and practice.

Membership in the Association is available at the following annual rates.

Full membership:

Membership dues of $205.00 include *Accounting Education News*, and the online selection of all three Association-wide journals: *The Accounting Review*, *Accounting Horizons*, and *Issues in Accounting Education*. (This does not include Section journals.) Full members may also opt to receive *hardcopies* of AAA journals for an additional cost:

The Accounting Review	with Print Option $45.00	Total U.S. $250.00
Accounting Horizons	with Print Option $25.00	Total U.S. $230.00
Issues in Accounting Education	with Print Option $25.00	Total U.S. $230.00
All three Association-wide journals	with Print Option $95.00	Total U.S. $300.00

Associate membership:

Full-time students are eligible for associate membership. The print option is not available for Associate members.

All three Association-wide journals	U.S. $35.00

In addition, full members may belong to one or more Sections: Accounting, Behavior and Organizations; Accounting Programs Leadership Group; American Taxation Association; Auditing; Diversity; Financial Accounting and Reporting; Forensic and Investigative Accounting; Gender Issues and Worklife Balance; Government and Nonprofit; Information Systems, International Accounting; Management Accounting; Strategic and Emerging Technologies; Teaching, Learning and Curriculum; and Two-Year College. Each Section assesses its own dues, which are collected by the Association.

Editorial correspondence and revisions of manuscripts originally submitted before June 1, 2011 should be sent via email to the incoming Senior Editor, John Harry Evans III, University of Pittsburgh, at tar@katz.pitt.edu • Telephone: (412) 624-8605 • Fax: (412) 648-1693. New manuscripts must be submitted through the Manuscript Submission and Peer Review System, located at http://accr.allentrack.net. The site contains detailed instructions regarding the preparation of files for submission.

The submission fee of $200.00 for members of the AAA or $400.00 for nonmembers may be paid online (VISA or MasterCard only) at https://aaahq.org/AAAforms/journals/tarsubmit.cfm and should be paid before the article is submitted.

Requests for information concerning membership, subscriptions, dues, advertisements, and other matters related to the Association (other than submission of manuscripts) should be sent to the American Accounting Association, 5717 Bessie Drive, Sarasota, FL 34233-2399 • Telephone: (941) 921-7747 • Fax: (941) 923-4093 • Email: Info@aaahq.org. Notice of change of address should be mailed at least eight weeks in advance to ensure undelayed receipt of *The Accounting Review*.

The Accounting Review is indexed in the Social Science Citation Index, which is included in Web of Science.

The Accounting Review (ISSN 0001-4826 print and ISSN 1558-7967 online) is published six times a year in January, March, May, July, September, and November by the American Accounting Association, 5717 Bessie Drive, Sarasota, Florida 34233-2399. General subscriptions are available at the annual rates of $410 for a print copy or at $465 for a print and an electronic copy. The member subscription rate for a hard copy is $35. Electronic access is included with membership dues. Periodicals Postage Paid at Sarasota, Florida and additional mailing offices. **POSTMASTER:** Send address changes to ***The Accounting Review***, 5717 Bessie Drive, Sarasota, Florida 34233-2399.

Is U.S. Multinational Dividend Repatriation Policy Influenced by Reporting Incentives?

Jennifer L. Blouin
University of Pennsylvania

Linda K. Krull
University of Oregon

Leslie A. Robinson
Dartmouth College

ABSTRACT: This study finds evidence that public-company reporting by U.S. multinational corporations (MNCs) creates disincentives to repatriate foreign earnings to the U.S. and contributes to the accumulation of cash abroad. MNCs operate under U.S. international tax laws and financial reporting rules and face two potential consequences when they repatriate foreign earnings: a cash payment for repatriation taxes and a reduction in reported accounting earnings. Using a confidential dataset of financial and operating characteristics of foreign affiliates of MNCs combined with public-company data, we examine how repatriation amounts vary across firms that face relatively strong reporting incentives to defer an accounting expense. Our results suggest that reporting incentives reduce repatriations by about 17 to 21 percent annually.

Keywords: *repatriation policy; reporting incentives; international tax policy.*

Data Availability: *Bureau of Economic Analysis (BEA) data were made available to the authors under a legal confidentiality arrangement; all non-BEA data are available from public sources.*

The authors thank Rosanne Altshuler, Fritz Foley, Matthew Slaughter, Ray Mataloni, and Bill Zeile for helpful suggestions regarding BEA data. The authors also thank Tom Omer and Harry Evans (editors), two anonymous reviewers, John Graham, David Guenther, Michelle Hanlon, Tim McDonald, Lillian Mills, Richard Sansing, Joel Slemrod, Doug Shackelford, Terry Shevlin, and participants at the 2009 UNC/KPMG Tax Research Symposium, 2009 UBCOW Conference, and 2009 *JATA* conference, and workshop participants at Northwestern University, University of California, Davis, Stanford University, Temple University, The University of Texas, Yale University, The University of Arizona, Arizona State University, Columbia University, and the University of Pennsylvania Wharton School for helpful comments. Professor Blouin appreciates the financial support from the Terker Research Fellowship awarded by the Rodney L. White Center for Financial Research.

The statistical analysis of firm-level data on U.S. multinational companies was conducted at the Bureau of Economic Analysis, Department of Commerce under arrangements that maintain legal confidentiality requirements. The views expressed are those of the authors and do not reflect official positions of the U.S. Department of Commerce.

I. INTRODUCTION

The U.S. tax system plays a role in the ability of U.S. multinational corporations (MNCs) to compete in the global marketplace. Various critics of U.S. international tax policy argue that the system of worldwide taxation has a negative effect on the competitiveness of U.S. firms and creates incentives to leave or "park" foreign profits overseas. Consistent with this incentive, MNCs held an estimated $403 billion of undistributed earnings in foreign countries at the end of 1999 (Brumbaugh 2003), which doubled to $804 billion by the end of 2004 (Redmiles 2008). As a result, policy makers and regulators have an interest in understanding factors that foster the accumulation of earnings in foreign countries.

Existing literature identifies several factors that contribute to this accumulation. Growing evidence that repatriations decrease when the tax cost of repatriating increases (e.g., Hines and Hubbard 1990; Altshuler and Newlon 1993; Altshuler et al. 1995; Grubert 1998; Desai et al. 2001; Desai et al. 2007) suggests that taxes are an important factor. Other evidence suggests that firms with high foreign profitability increase both foreign retained earnings and dividend repatriations (Grubert 1998), and that firms with domestic financing needs, domestic investment needs, and intra-firm agency problems repatriate more foreign earnings (Desai et al. 2007).

More recently, accounting research investigates how accounting for income taxes contributes to the accumulation of foreign earnings abroad. Shackelford et al. (2011) model the effect of financial reporting on firms' real decisions and note that repatriation is an area for which such forces have potential importance. Graham et al. (2011) find that, when asked which factors are important in the decision to reinvest foreign earnings outside of the U.S., executives rate the importance of deferring an accounting expense for repatriation taxes as high as deferring a cash payment for repatriation taxes. We explore this issue in more detail by studying the extent to which reporting incentives to defer an accounting expense affect managers' actual repatriation decisions.[1]

As discussed in the "Repatriation and Tax Law" section, tax laws prescribe the amount and timing of cash payments for U.S. taxes on repatriations of foreign earnings, whereas accounting rules, described in the "Repatriation and Financial Reporting Rules" section, prescribe the amount and timing of the income tax expense recorded in the financial statements. Tax laws require MNCs to pay repatriation taxes when a foreign affiliate remits its earnings as a dividend to the U.S. parent.[2] Financial reporting rules require MNCs to recognize a repatriation tax expense for actual or expected repatriation taxes when earnings are generated in foreign affiliates, regardless of whether they are repatriated. However, an exception to this general rule (hereafter, the Indefinite Reversal Exception) allows them to defer recognition of a repatriation tax expense until repatriation if the earnings are indefinitely reinvested abroad (hereafter, permanently reinvested earnings or PRE).

The Indefinite Reversal Exception introduces financial reporting consequences to repatriation for MNCs that routinely utilize the PRE designation. Specifically, when an MNC reinvests foreign earnings and designates them as PRE, it recognizes foreign pre-tax earnings with no corresponding repatriation tax expense. If the MNC eventually repatriates the earnings, then it must recognize a repatriation tax expense with no corresponding pre-tax earnings, potentially decreasing after-tax earnings. As a result, the Indefinite Reversal Exception creates reporting incentives to defer repatriation incremental to the cash tax incentive documented in existing literature.

---

[1] We obtain the data for this study from the Bureau of Economic Analysis (BEA) *Survey of U.S. Direct Investment Abroad*. Participation in the BEA surveys is mandated by federal law pursuant to the International Investment and Trade in Services Survey Act (P.L. 94-472, 90 Stat. 2059, 22 U.S.C. 3101-3108) and willful failure to participate can result in monetary fines and/or imprisonment. Furthermore, the BEA staff reviews the survey responses. However, as with any data source, errors occur and compliance may be less than 100 percent. See Mataloni (2003) and http://www.bea.gov/surveys/diasurv.htm for detailed information on BEA data.

[2] The BEA defines a foreign affiliate as a foreign business enterprise in which there is direct or indirect equity investment of more than 10 percent by a U.S. entity. An affiliate can be any organization, association, branch, estate, trust, venture, or subsidiary that exists to make a profit. However, we use the term foreign affiliate to refer only to foreign subsidiaries over which the U.S. parent has control, i.e., greater than a 50 percent equity investment.

These reporting incentives vary across firms in at least two ways. First, existing research finds that some firms have a stronger focus on reported earnings than do other firms. For example, evidence suggests that public firms are more likely than private firms to use accounting methods and tax-planning methods that increase earnings (Penno and Simon 1986; Cloyd et al. 1996; Badertscher et al. 2011) and, among public firms, those with greater ownership by dedicated investors exhibit a lesser tendency to fixate on earnings (Bushee 1998). Second, the magnitude of the earnings effect of repatriation will vary depending on a firm's use of the Indefinite Reversal Exception. All else equal, firms that have designated more undistributed foreign earnings as PRE have a larger unrecognized tax expense and a greater potential to experience a decrease in earnings upon repatriation.

We use this variation to develop two categories of proxies that capture the magnitude of reporting incentives to defer repatriation. The first category, our capital markets measures, captures the magnitude of any anticipated negative capital market response to the repatriation tax expense. Within this category, we estimate two measures of reporting incentives. Our first measure captures public versus private firm ownership because the financial reporting literature suggests that private firms are relatively less sensitive to capital market pressures (e.g., Cloyd et al. 1996; Penno and Simon 1986; Wolfson 1993; Graham et al. 2011). Therefore, on average, public firms face greater reporting incentives to avoid repatriation than private firms. Our second measure combines several proxies that capture the extent to which public firm managers believe that their firms' earnings face relatively more intense capital market scrutiny—earnings response coefficients, the firm's history of meeting analyst expectations, and ownership by dedicated investors. On average, we expect managers to have stronger reporting incentives to avoid repatriation as earnings response coefficients increase (because the stock price decrease will be larger per dollar of repatriation tax expense), as the history of meeting analyst forecasts improves (because the firm's history of meeting analyst forecasts suggests a greater concern about earnings) and as the proportion of shares held by dedicated institutional investors decreases (because these investors are more sophisticated financial statement users with a long-term focus).

The second category of proxies for reporting incentives, our earnings measure, uses PRE to identify firms with a relatively large unrecognized tax expense and therefore a greater potential to experience an earnings decrease when repatriating. Upon repatriation, firms that routinely designate foreign earnings as PRE must recognize a tax expense that they regularly deferred under the Indefinite Reversal Exception. Thus, we expect that reporting incentives to avoid repatriation are, on average, greater for firms that make extensive use of the PRE designation.

The effects of tax laws and financial reporting rules on repatriations are interrelated because the cash payment for repatriation taxes and the financial statement expense for repatriation taxes both depend on the repatriation tax rate. Due to this interdependence, we test whether firms are more sensitive to the repatriation tax rate as reporting incentives to defer repatriation increase in magnitude.

We test our predictions using a sample of 479 public and 98 private MNCs from 1999 through 2004. After controlling for investment opportunities, size, financing constraints, tax planning, and country-level attributes, we find that repatriation by public firms is more sensitive to the repatriation tax rate than repatriation by private firms. We also find that repatriation by public firms for which the recognition of a repatriation tax expense is expected to affect firm value more negatively is more sensitive to the repatriation tax rate than repatriation by other public firms. Finally, repatriation by public firms that make extensive use of the PRE designation under the Indefinite Reversal Exception is more sensitive to the repatriation tax rate than repatriation by other public firms. Our estimates suggest that firms with high reporting incentives repatriate, on average, 16.6 to 21.4 percent less per year than firms with low reporting incentives. This estimate amounts to a total of $6.7 billion annually for our sample of public firms and $1.5 billion annually for public firms with high amounts of PRE.

We evaluate the robustness of our results and the adequacy of our proxies for reporting incentives using two additional analyses. First, we conduct subsample analyses and find that the sensitivity of repatriation to the repatriation tax rate is greater when firms are more likely to recognize repatriation tax expense upon repatriation and anticipate a negative capital market response to this expense. Second, we extend Foley et al. (2007) to show that the effect of repatriation taxes on the accumulation of foreign cash in public companies is exacerbated by reporting incentives. Collectively, our empirical results consistently demonstrate that reporting incentives deter repatriation of foreign earnings.

This study makes important contributions to the literature by informing the broader policy debate about necessary reforms to our international tax system and by aiding our understanding of how accounting for income taxes affects repatriation behavior. The accounting literature has only very recently begun to explore the effect of accounting standards on repatriation decisions. Graham et al. (2011) provides useful initial insight by surveying executives. While their evidence tells us what managers believe is important with respect to repatriation taxes, we study whether financial accounting consequences have an economically meaningful effect on managers' actions. Specifically, we identify and measure the mechanisms that create reporting incentives to defer recognition of the repatriation tax expense and estimate the magnitude of their effect on repatriation amounts. Thus, our results shed light on the extent to which accounting standards contribute to the growing pool of undistributed foreign earnings that U.S. firms hold in foreign countries.

Section II provides a background and develops our hypotheses. Sections III and IV describe our data and our research design, respectively. Section V discusses our main results and Section VI provides results from supplemental analyses. Section VII concludes.

II. BACKGROUND AND HYPOTHESES

We analyze how tax laws and financial reporting rules interact to influence repatriation decisions. Therefore, to motivate our hypotheses, we first describe the tax and financial reporting rules that govern the repatriation of foreign earnings.

Repatriation and Tax Law

When a foreign affiliate pays a dividend to its U.S. parent, the amount of repatriation taxes equals the dividend grossed-up for foreign taxes paid times the U.S. statutory tax rate minus the foreign tax credit. Generally, the foreign tax credit equals the amount of foreign taxes paid on the foreign earnings up to the amount of the U.S. tax liability. If the foreign tax rate is greater than the U.S. tax rate, then the MNC owes no incremental U.S. taxes on repatriated earnings. Further, if an MNC repatriates earnings from more than one country, then it can use tax credits generated in high-tax countries to offset U.S. taxes on repatriations from low-tax countries. Therefore, the incremental tax rate on repatriation can be thought of as the difference between the U.S. tax rate and the average foreign tax rate paid on repatriated foreign earnings.

From a tax perspective, an MNC with foreign earnings has two choices. It can reinvest the earnings abroad or repatriate the earnings. When the MNC reinvests the earnings abroad, the current taxes paid on foreign earnings consists only of foreign income taxes. Alternatively, when the MNC repatriates the earnings, the current taxes paid on foreign earnings consists of both foreign income taxes and U.S. repatriation taxes. Thus, *tax laws—not financial reporting rules—determine when firms pay repatriation taxes.*

Existing work on repatriation decisions finds that repatriations are negatively related to the repatriation tax rate. Hartman (1985) shows theoretically that, when after-tax returns and tax rates are constant over time, the repatriation tax rate does not affect the repatriation decision because all foreign earnings will eventually be taxed at the U.S. tax rate. However, subsequent empirical evidence suggests that repatriations are decreasing in the repatriation tax rate (e.g., Hines and Hubbard 1990; Altshuler and Newlon 1993; Grubert 1998; Desai et al. 2001, 2007). Altshuler et al. (1995) reconcile theoretical work with empirical evidence by recognizing that tax rates are not constant over time. The authors estimate transitory and permanent components of firms' repatriation tax rates and find that dividend repatriations are negatively related to the transitory component and are not related to the permanent component. In contrast to evidence that U.S. tax law generally deters repatriation, Altshuler and Grubert (2003) describe sophisticated tax-planning strategies that allow low-tax affiliates to avoid repatriation taxes, but note that this type of tax planning is costly.

Repatriation and Financial Reporting Rules

From a financial reporting perspective, an MNC that reinvests foreign earnings abroad has two choices. The MNC can either currently recognize an expense for expected repatriation taxes on current earnings or it can use the Indefinite Reversal Exception to defer recognition of a repatriation tax expense until it repatriates the earnings.[3] Thus, *financial reporting rules—not tax laws—determine when firms recognize the financial statement expense for repatriation taxes.*

Once a firm designates foreign earnings as PRE, repatriation of these earnings in a subsequent accounting period will, all else equal, decrease earnings relative to prior periods because it must recognize the repatriation tax expense that it deferred in prior years. As a result, accounting expense recognition is an additional consequence of repatriation when firms repatriate earnings that were previously designated as PRE.

Some MNCs use the PRE designation extensively. To illustrate, Bear Sterns and Company (2005) find that the S&P 500 report $420 billion of PRE at the end of 2002, and Zion et al. (2010) find that these firms report nearly $1 trillion of PRE at the end of 2008. In addition, existing research finds evidence that deferral of the financial statement expense for repatriation taxes is an important factor in the decision to designate undistributed foreign earnings as PRE. Krull (2004) finds that MNCs increase amounts designated as PRE, thereby deferring recognition of the repatriation tax expense, in order to maximize reported after-tax earnings and meet earnings benchmarks. Graham et al. (2011) report that the extent to which MNCs utilize the PRE designation is positively associated with how important they rate expense deferral and negatively associated with how important they rate cash tax deferral. Evidence from both studies suggests that deferral of the repatriation tax expense is an important motivation in the decision to use the Indefinite Reversal Exception.

Hypotheses

As we discuss in the "Repatriation and Tax Law" section, existing research finds evidence that repatriation taxes deter repatriation. To examine whether reporting incentives also deter repatriation, we identify and measure firm attributes across which reporting incentives vary while holding the cash payment for repatriation taxes constant. Because the purpose of our study is to explain a continuous accumulation of funds abroad, we use measures that are designed to capture a type of firm that faces either greater capital market pressure to consistently report strong earnings or a greater potential to experience an earnings decrease when repatriating. We do not include measures that capture incentives to time expense recognition, such as variables that capture incentives to beat an earnings benchmark in a specific period, because the timing of repatriations from one year to the next likely represents small differences in overall repatriations that cannot explain an accumulation of funds abroad. With this purpose in mind, we characterize our measures of reporting incentives as capital market measures that capture an anticipated negative capital market response to the repatriation tax expense or as earnings measures that reflect a firm's potential for experiencing an earnings decrease when repatriating.

---

[3] FASB ASC 740 (2009) contains both the general rule requiring MNCs to recognize an expense for expected repatriation taxes and the Indefinite Reversal Exception.

We begin by investigating hypotheses on whether capital market incentives deter repatriation. We first use public versus private firm ownership as a measure of the anticipated negative capital market response to the repatriation tax expense. This capital market measure allows reporting incentives to vary while holding the cash payment for repatriation taxes relatively constant because both public and private firms are subject to the same tax laws, but capital market pressures vary between public and private firms due to differences in the constituents to which the two types of firms report. Specifically, public firm managers have private information, report to current and potential investors, and are evaluated on their performance based on the information they provide. Therefore, public firm managers typically have a strong focus on reported earnings because of its effect on both firm value and managerial compensation (e.g., Cloyd et al. 1996; Penno and Simon 1986). In contrast, private firms have high levels of insider ownership and encounter less information asymmetry between managers and investors. Therefore, private firm managers have relatively less incentive to focus on reported earnings (Beatty and Harris 1999).

Several studies empirically test this conjecture. Using survey evidence, Penno and Simon (1986) find that public firms are more likely than private firms to choose financial accounting methods that increase earnings. Consistent with this evidence, Cloyd et al. (1996) and Badertscher et al. (2011) find that public firms are more likely than private firms to choose financial accounting methods and/or tax-planning methods that result in higher earnings on the financial statements. The results of these studies suggest that public firms place a stronger focus on increasing accounting earnings than private firms. More closely related to our study, Graham et al. (2011) find that more public firms than private firms rate the financial statement expense for repatriation taxes as important in the repatriation decision. All else equal, we expect that the potential recognition of a repatriation tax expense will have a more negative impact on public firm repatriations than private firm repatriations.

Both the cash payment for repatriation taxes and the financial statement expense for repatriation taxes depend on the repatriation tax rate. Therefore, after controlling for other determinants of repatriation, if public firms are more sensitive to the repatriation tax rate than private firms, then we can attribute this incremental sensitivity to reporting incentives.

> **H1A:** *Ceteris paribus*, repatriation by public firms is more sensitive to the repatriation tax rate than repatriation by private firms.

Because unobservable differences between public and private firms may affect the sensitivity of repatriation to tax costs, we develop another measure of the anticipated negative capital market response to repatriation tax expense to exploit cross-sectional variation in reporting incentives among public firms. This measure identifies public firms for which we expect a repatriation tax expense to have a more negative effect on firm value. This test focuses on the potential stock price response to a repatriation tax expense as an alternative capital market measure of reporting incentives.

The existing capital markets literature develops many measures that capture various aspects of a potential stock price response to the firm's accounting earnings. Because the purpose of this study is to explain a continuous accumulation of funds outside the U.S., we select three of these measures to capture a diverse set of factors that create consistent pressure to report strong earnings numbers: earnings response coefficients, the firm's history of meeting analyst forecasts, and ownership by dedicated institutions.

The first measure is the firm's long-window earnings response coefficient (ERC). The ERC is "the most common empirical measure of investor responsiveness" to earnings (Dechow et al. 2010). We use this variable to capture the extent to which the manager is more likely to believe that tax expense recognition will negatively impact stock price.[4] As ERCs increase, a firm's price-sensitivity to a repatriation tax expense increases.

The second measure is the proportion of all previous quarters that a firm appears in I/B/E/S for which it beat the median analyst EPS forecast by one cent or less (Carter et al. 2007; Degeorge et al. 1999). Prior studies find that firms enjoy a stock market premium that increases in their tendency to meet analyst expectations, creating situations in which managers act as if sustaining these patterns will prevent a negative capital market response (e.g., Degeorge et al. 1999; Abarbanell and Lehavy 2003). Tax expense recognition upon repatriation of foreign earnings can cause a firm to miss an analyst forecast, resulting in a reversal of this premium. Therefore, firms with a more consistent history of meeting earnings forecasts are likely to have a higher price-sensitivity to a repatriation tax expense.

The third measure of the potential stock price response to a repatriation tax expense is the proportion of the firm's stock held by long-term institutional investors (Bushee 1998). Bushee (1998) classifies institutional investors based on the extent to which they likely influence myopic behavior by firm managers. Dedicated investors alleviate pressures for myopic behavior (e.g., reducing R&D or repatriations to meet earnings goals) because their large, long-term holdings create incentives to monitor managers and rely on information other than earnings to assess performance. As dedicated investor ownership increases, the firm will likely experience a lower price-sensitivity to expense recognition because investors, and therefore managers, focus less on short-term earnings and more on longer term economic consequences of current period decisions.

Assuming managers want to maximize the firm's stock price, we expect that firms whose stock price will decrease more per dollar of expense will be more sensitive to a repatriation tax expense. Firms with higher ERCs, more consistent histories of beating analyst forecasts, or lower ownership by dedicated institutions face a potentially larger decrease in stock price per dollar of repatriation tax expense. We expect that this higher price-sensitivity to earnings will make these firms' repatriation decisions more sensitive to the repatriation tax rate. Therefore we predict the following:

> **H1B:** *Ceteris paribus*, repatriation by public firms with high price-sensitivity to earnings is more sensitive to the repatriation tax rate than repatriation by other public firms.

Next, we investigate whether earnings incentives deter repatriations. This test uses a measure that identifies firms for which the earnings effect of repatriations is expected to be relatively high. We identify the extent to which each public MNC in our sample relies on the Indefinite Reversal Exception by obtaining PRE disclosed in financial reports. This test also focuses on public firms because we can only observe PRE disclosures from Securities and Exchange Commission (SEC) filings.

We use PRE to measure reporting incentives to defer repatriations because the cash payment for repatriation taxes is independent of the firm's level of PRE, but the financial statement expense varies directly with the level of PRE. Thus, a firm's level of PRE is a direct measure of the potential financial reporting consequence of repatriation. All else equal, the firm's unrecognized repatriation tax expense increases in PRE. Therefore, MNCs with high amounts of PRE have a greater potential to recognize a tax expense upon repatriation than firms with low amounts of PRE. Even if an MNC only repatriates current earnings, if it previously designated high levels of undistributed foreign earnings as PRE, then, all else equal, it will have a higher tax expense and lower earnings compared to prior periods. Furthermore, MNCs that have designated all of their undistributed foreign earnings as PRE cannot avoid tax expense recognition in their financial statements by repatriating non-PRE foreign retained earnings while firms with low or no PRE can.[5]

---

[4] See Kothari (2001) and Dechow et al. (2010) for a review of research in this area.

Thus, we expect that firms repatriate less as the unrecognized repatriation tax expense related to the firm's PRE increases. As in our tests of H1A and H1B, if after controlling for other determinants of repatriation, repatriation by firms that use PRE extensively is more sensitive to the repatriation tax rate than other firms, then we can attribute this incremental sensitivity to reporting incentives. Hence, we test the following hypothesis:

> **H2:** *Ceteris paribus*, repatriation by public firms that rely extensively on the PRE designation under the Indefinite Reversal Exception is more sensitive to the repatriation tax rate than repatriation by other public firms.

III. DATA

Examining whether reporting incentives affect the repatriation decisions of MNCs necessitates measuring repatriations, the repatriation tax rate, and reporting incentives. We obtain repatriation amounts and data required to estimate the repatriation tax rate from the *Survey of U.S. Direct Investment Abroad* conducted by the Bureau of Economic Analysis (BEA) each year since 1982. Federal law obligates MNCs to report certain financial and operating data for both domestic and foreign operations to the BEA. An MNC is the combination of a single U.S. entity, called the U.S. parent, and at least one foreign affiliate. The amount of information collected by the BEA varies by year and by affiliate because more detailed information is collected in benchmark years, which occur every five years (1999 and 2004 in our sample), and only affiliates that meet the applicable reporting threshold are required to report.[6]

MNCs report to the BEA on a fiscal-year basis and follow U.S. Generally Accepted Accounting Principles (GAAP) except consolidation rules. The BEA requires that the U.S. parent use the equity method of accounting for its foreign affiliates, whereas GAAP requires consolidation for ownership interests greater than 50 percent. This unique feature of the data allows us to separately identify foreign and domestic financial data (e.g., foreign assets), which is necessary to compute many of our regression variables. The BEA data also enable us to aggregate financial data across the U.S. parent and its foreign affiliates to compute firm-level variables (e.g., worldwide assets). To avoid double-counting, we eliminate intercompany accounts (e.g., assets, sales, and income) reported by the MNC to the BEA.[7]

---

[5] Suppose that there are two U.S. multinational firms (A and B) and each has $900 of unremitted foreign earnings and pays $100 of foreign taxes. In addition, both firms earn $650 ($1,000) after-tax (pre-tax) domestically. Upon repatriation of the earnings to the U.S., each firm will have a $250 repatriation tax liability. Assume that Firm A always asserts that its unremitted foreign earnings are PRE, whereas Firm B never makes this assertion. Under these facts, Firm A has an effective tax rate (ETR) of 22.5 percent (450/2000) whereas Firm B has an ETR of 35 percent [(450 + 250(accrued repatriation expense))/2000]. When earnings are repatriated in a subsequent period, Firm A will recognize an additional $250 tax expense but Firm B will not. As a result, Firm A's ETR will be higher than 22.5 percent, whereas Firm B will continue to have a 35 percent ETR. In addition, if at any point in the future Firm A ceases making the PRE designation (perhaps because it intends to repatriate current earnings), then its ETR will increase as compared to prior years. Notice that as a firm's PRE increases, the potential earnings impact of repatriation increases. Said another way, the more PRE a firm has, the less flexibility it has to repatriate without an unfavorable change in its ETR.

[6] In order to reduce the reporting burden, the BEA only requires affiliates to participate if its assets, sales, or net income (loss) exceed the threshold for the year. The thresholds are higher in non-benchmark years, thus requiring fewer affiliates to report. Thresholds are $7 million in 1999, $30 million in 2000–2003, and $10 million in 2004. During the 2000–2003 non-benchmark years, most of the financial and operating data that we observe for affiliates that are not required to participate in the survey are estimated by the BEA. We use only reported data, not estimated data, in our analyses.

We combine BEA data with other data sources to construct measures of reporting incentives. Specifically, we determine public versus private ownership status for our sample of BEA firms using Compustat and the LexisNexis Corporate Affiliations database.[8] For tests that feature only public firms, we calculate ERCs using CRSP data, the percentage of quarters the firm beat analyst forecasts using I/B/E/S data, and dedicated institutional ownership using the Bushee (1998) classification. We obtain PRE from SEC filings.

Table 1, Panel A describes our sample selection process. To construct our sample, we identify MNCs that appear in the BEA data and have at least one foreign affiliate reporting for six consecutive years from 1999 through 2004. These restrictions limit our sample to MNCs with significant foreign operations and create a time period that includes two benchmark years. A total of 4,840 MNCs (57,164 affiliates) appear at least once in the BEA data from 1999 to 2004. Of these, only 805 MNCs (33,196 affiliates) have at least one affiliate reporting in all six years. We further restrict the sample by eliminating ADRs and foreign incorporated parents that are not likely to be constrained by either U.S. tax law or U.S. financial reporting rules when paying dividends to U.S. entities; we also eliminate banks and utilities.[9] Finally, we eliminate pass-through entities (e.g., partnerships, LLCs, and REITS) since they are typically not subject to corporate income taxes. Our final sample consists of 577 MNCs (25,459 affiliates); 479 MNCs (23,669 affiliates) are public and 98 MNCs (1,790 affiliates) are private. From this balanced panel, we eliminate 285 firm-years for which we do not have all required regression variables for our multivariate analyses resulting in 3,177 firm-years. Table 1, Panel B suggests that broad industry representation is present in our sample, with a heavy emphasis on textiles, manufacturing, and retail.

IV. RESEARCH DESIGN

Our hypotheses predict that firms are more sensitive to the repatriation tax rate in the presence of reporting incentives. We test our hypotheses by empirically estimating annual repatriations as a function of the estimated repatriation tax rate, a proxy for reporting incentives, an interaction term, and economic incentives to repatriate as follows:

$$\begin{aligned} Repatriations = {} & \beta_0 + \beta_1 RepTR + \beta_2 Reporting\ Incentives + \beta_3 Reporting\ Incentives \times RepTR \\ & + \sum \beta_k Controls_k + \sum \beta_t Year_t + \sum \beta_j Industry_j + \varepsilon \end{aligned} \tag{1}$$

where:

---

[7] For example, under the equity method of accounting used for BEA reporting, total assets of the U.S. parent includes the "net assets" of its foreign affiliates. However, this amount is reported as a separate line item on the balance sheet of the U.S. parent, allowing us to eliminate intercompany assets without introducing measurement error in our calculation of worldwide assets. For our sample of public firms, the correlation between worldwide assets using Compustat data and worldwide assets using BEA data is 0.98 ($p < 0.01$), and for net income the correlation is 0.99 ($p < 0.01$). Our repatriations measure only captures dividends paid to the U.S. parent directly from a foreign affiliate, which avoids a double-counting problem with this variable.

[8] We identify public companies in the BEA data by matching with Compustat on company name and verifying private ownership using the LexisNexus Corporate Affiliations database.

[9] Firms operating in these industries are likely to have more opportunities to avoid repatriation taxes by redeploying capital around the world, and they face different incentives than other firms because they are regulated. As a practical matter, we are also unable to compute many of our regression variables for banks because the BEA collects substantially less data for these entities than for other entities because they report to other government agencies.

TABLE 1

Sample Composition

Panel A: Bureau of Economic Analysis

	Affiliates	Parents
In BEA data between 1999 and 2004	57,164	4,840
Less parents without 6 consecutive years of data	(12,709)	(2,283)
Less parents without 6 consecutive years of affiliate reporting	(11,259)	(1,752)
Less ADRs	(519)	(22)
Less foreign incorporated parents	(1,399)	(48)
Less banks and insurance companies	(3,433)	(65)
Less pass-through entities	(409)	(10)
Less public entities not in Compustat for 6 consecutive years	(1,126)	(61)
Less firms missing BEA data	(147)	(8)
Less firms whose parents cannot be identified[a]	(704)	(14)
Total	25,459	577
Private Entities	1,790	98
Public Entities	23,669	479

Panel B: Industry Composition of Sample

	Private	Public
1. Mining and construction	Combined	3.5%
2. Food	10.2%	4.4%
3. Textiles, printing, and publishing	13.3%	12.1%
4. Chemicals	10.2%	8.4%
5. Pharmaceuticals	Combined	2.3%
6. Extractive industries	7.1%	5.0%
7. Durable manufacturing	22.5%	25.5%
8. Computers	5.1%	12.1%
9. Transportation	5.1%	5.4%
11. Retail	13.3%	16.5%
13. Insurance and real estate	Combined	Combined
14. Services	7.1%	3.8%
15. Other and combined low reporting industries[b]	6.1%	1.0%

[a] Includes four mutual companies, four firms that changed status during the sample period (i.e., public to private, foreign ownership to domestic ownership) and six firms whose parents we could not identify as domestic or foreign owned.

[b] Any industries with less than five observations are combined with the "Other" category.

Repatriations = current-year repatriations scaled by worldwide assets;

RepTR = estimate of the rate of tax the firm would owe to the U.S. if it repatriated all undistributed foreign earnings, computed as the U.S. statutory tax rate (35 percent) minus *Creditable Tax Rate*;[10] and

Reporting Incentives = 1 for firms that face relatively high reporting incentives, and 0 otherwise.

---

[10] See Appendix A for a detailed definition of this variable. This measure improves upon existing estimates of the incremental taxes due upon repatriation that use current period foreign tax rates because it is estimated in a manner similar to the U.S. foreign tax credit computation under Section 902 of the Internal Revenue Code. A detailed example of this calculation is available from the authors.

See Appendix A for definitions of all other variables.

We estimate Equation (1) at the firm level because the variables of interest, *RepTR* and *Reporting Incentives*, are firm-level constructs. We use a Tobit model for this estimation because roughly 55 percent of the observations in our sample exhibit *Repatriations* of 0.[11] *RepTR* is a measure of the firm's repatriation tax rate. Consistent with existing literature, we expect a negative coefficient on *RepTR*. For our hypotheses, our focus is on the interaction between *RepTR* and *Reporting Incentives* that tests whether repatriation is more sensitive to the repatriation tax rate in the presence of reporting incentives.

We use three proxies for reporting incentives—*Public*, *CapMkt*, and *HighPre*. Our test of H1A uses *Public*, which equals 1 for firms with public equity, 0 otherwise.[12] Our test of H1B requires that we identify a sample of public firms with a high price-sensitivity to earnings. Since all public firms face some degree of capital market pressure from various sources that create this sensitivity, we construct a composite measure that allows us to simultaneously consider multiple sources of capital market pressure: (1) investor responsiveness to earnings, estimated using earnings response coefficients (hereafter, *ERC*); (2) pressure to beat analyst forecasts, estimated by the proportion of quarters that the firm appears in I/B/E/S for which it beat the median analyst EPS forecast by one cent or less (hereafter, *BEAT*); and (3) the likelihood of investor-induced myopic behavior of managers, estimated by the proportion of stock owned by dedicated institutions (hereafter, *DED*).[13] *CapMkt* equals 1 for firms with an *ERC* in the top quartile of the sample, *BEAT* in the top quartile, or *DED* in the bottom quartile, 0 otherwise.[14] This approach increases the power of our test while allowing us to maintain a sufficient number of observations in both high ($CapMkt = 1$) and low ($CapMkt = 0$) reporting incentive subsamples.

To test H2 we must identify a subsample of public firms with the most significant unrecognized repatriation tax expense and therefore the greatest potential earnings effect of repatriation. We identify these firms by setting *HighPre* equal to 1 if PRE equals or exceeds total assets in low-tax affiliates (i.e., affiliates with *Affiliate Creditable Tax Rate*, defined in Appendix A, less than or equal to 30 percent) in either 1999 or 2004, and 0 otherwise.[15]

---

[11] Tobin (1958) originally introduced the Tobit model in the context of censored data, i.e., where data on the dependent variable are lost (or limited) but data on the independent variables are not. Since the seminal work of Tobin, econometricians have clarified that the Tobit model is also appropriately used to analyze "corner solutions," a data structure similar to censored data where the dependent variable takes on the value of zero for a significant proportion of the sample (Wooldridge 2002; Greene 2003). Note that in the corner solution setting, the issue is not the inability to observe data. Numerous public finance economists have used the Tobit model in the context of repatriations (e.g., Hines and Hubbard 1990; Altshuler and Newlon 1993).

[12] Note that we eliminate less than ten MNCs in the BEA data that have public debt but not public equity as it was unclear whether these firms should be classified as public or private firms.

[13] To estimate ERCs, we measure the relation between accounting earnings and security returns using the association, or long-window, approach (e.g., Collins and Kothari 1989; Kormendi and Lipe 1987). Chaney and Jeter (1992) document that long-window rather than short-window ERCs better measure this relation for large firms because there is a greater flow of nonaccounting information between releases of earnings reports.

[14] While this measure incorporates multiple reasons a firm might face capital market pressure into a single variable and therefore captures more information about reporting incentives, it places equal weight on each variable, potentially introducing measurement error. To address this potential, we report results using each component of *CapMkt* separately in the "Earnings Measures of Reporting Incentives" section.

[15] Scaling PRE by assets in low-tax affiliates assumes that all PRE is in low-tax affiliates. In sensitivity tests we scale PRE by total foreign assets, which assumes that PRE is allocated proportionately across high- and low-tax affiliates. Our results are not sensitive to scaling PRE by total foreign assets or other definitions of this variable as discussed in the "Earnings Measures of Reporting Incentives" section. We use benchmark years (1999 and 2004) to define *HighPre* because MNCs disclose PRE at the firm-level in SEC filings, but report foreign assets at the affiliate-level in BEA data. More affiliates report in benchmark years because BEA reporting thresholds are lower in those years (described in Section III). Using only benchmark years to define PRE allows us to compare a firm-level variable to the most comprehensive estimate of foreign assets. Since the use of PRE is highly persistent, i.e., firms seldom report decreases in PRE, we identify firms that use PRE extensively as those that meet this threshold in either 1999 or 2004.

Three factors motivate our definition of *HighPre*. First, we assume that most PRE relates to activity in low-tax affiliates. Firms have no clear motivation for invoking the PRE designation for foreign earnings that they do not expect to generate a repatriation tax expense upon repatriation. Therefore, as PRE increases relative to assets in low-tax affiliates, the likelihood that a firm can repatriate without recognizing a repatriation tax expense decreases. Second, using a high threshold as a benchmark to construct an indicator variable, rather than using a continuous measure of PRE, ensures that repatriation will have an earnings effect for the subsample of firms we label *HighPre*. Firms with some undistributed foreign earnings that are *not* PRE have the ability to repatriate with no earnings effect.[16] Third, PRE technically arises from basis differences for book and tax purposes; a significant proportion of basis differences arise from undistributed foreign earnings, but these differences can arise from other sources such as the purchase of an affiliate that results in different book and tax bases in the firm's stock. Using assets allows for the possibility that some PRE arises from basis differences other than foreign retained earnings.[17]

Because public firms (i.e., $Public = 1$) face greater capital market pressure than private firms, public firms with high price-sensitivity to earnings (i.e., $CapMkt = 1$) face a more negative stock price response to a dollar of a repatriation tax expense than other public firms, and public firms with high amounts of PRE ($HighPre = 1$) deferred recognition of more repatriation tax expense. H1A, H1B, and H2 predict that repatriation by these firms is more sensitive to the repatriation tax rate than repatriation by other firms. All else equal, we expect negative coefficients on $Public \times RepTR$, $CapMkt \times RepTR$, and $HighPre \times RepTR$.

In addition to our variables of interest, we include controls for other factors that influence repatriation decisions. First, we include controls for investment opportunities abroad and in the U.S. (*Foreign ROA* and *U.S. ROA*, respectively). Hartman (1985) argues that firms will invest earnings in operations with the highest after-tax return by repatriating only when the after-tax return on foreign investment is less than the after-tax return on domestic investment. This theoretical result suggests that repatriations are negatively related to foreign investment opportunities and positively related to domestic investment opportunities. However, firms with more profitable foreign operations have more funds available to repatriate, suggesting a positive coefficient on *Foreign ROA*. Likewise, firms with profitable domestic operations have more domestic funds available for investment in the U.S., suggesting a negative coefficient on *U.S.ROA*. Thus, we make no prediction for the coefficients on *U.S. ROA* or *Foreign ROA*.[18]

We include *Indirect Ownership* and *Holding Company* to control for cross-sectional variation in the sophistication of firms' international tax-planning strategies. These variables control for a potential self-selection problem with respect to *Public* and *HighPre*. Specifically, evidence exists that public and private firms face different financial and tax reporting trade-offs that affect the type and amount of tax planning they undertake. For example, Beatty and Harris (1999) and Mikhail (1999) find evidence that private firms are more aggressive tax planners than public firms. In addition, Hanlon et al. (2007) link private ownership to greater proposed income tax deficiencies with the IRS than public ownership. Further, some firms may designate foreign earnings as PRE because they are invested in sophisticated tax-planning strategies. These relationships could bias the coefficients on *Public* × *RepTR* and *HighPre* × *RepTR* up or down depending on the effect of tax planning on repatriations.

---

[16] See footnote 5 for a specific example.

[17] The Indefinite Reversal Exception applies broadly to outside basis differences, i.e., differences in the book and tax bases of a firm's stock in its affiliate (BNA 2010). Many outside basis differences have potential U.S. tax consequences upon repatriation but are not reflected in retained earnings. Therefore, assets better captures the broader concept of PRE than retained earnings.

[18] Hartman (1985) suggests that the difference between these two variables, *U.S. ROA* – *Foreign ROA*, should be included as an explanatory variable. We include them separately, which is similar to including the difference but allows the coefficients on the two variables to differ.

Sophisticated tax planning will increase repatriations if the strategy allows for tax-efficient repatriation. For example, Altshuler and Grubert (2003) describe strategies that allow the U.S. parent to effectively convert income earned in low-tax affiliates into high-tax income that can be repatriated tax free. Conversely, tax planning will decrease repatriations if the strategy calls for long-duration foreign investment projects to defer the U.S. tax liability (Desai et al. 2003). The strategies described in Altshuler and Grubert (2003) and Desai et al. (2003) use tiered-ownership in which the parent indirectly owns a foreign affiliate through another foreign affiliate. These strategies also use indirect ownership of a foreign affiliate through a holding company, which is an affiliate that does not produce goods or services, but is created solely to own another affiliate. Thus, we control for the sophistication of a firm's tax planning using two measures of the extent to which the firm uses tiered-ownership. Following Desai et al. (2003), we define *Indirect Ownership* as the proportion of the firm's foreign affiliates that are indirectly owned. Similarly, we define *Holding Company* as the proportion of the firm's foreign affiliates that are holding companies (i.e., those with North American Industry Classification System code 5512). Because these tax-planning strategies can increase or decrease repatriations, we do not make a sign prediction for these variables.

Equation (1) also includes controls for the size of foreign operations, agency costs, financing constraints, and costs of financing. *Size* equals the natural log of foreign sales. We expect a positive coefficient on *Size* because firms with larger foreign operations have more funds available to repatriate. We include *U.S. Leverage* and *Foreign Leverage* to control for firms' debt service needs and capital structure. Firms may be more reluctant to repatriate if they have high foreign debt service, suggesting a negative association between *Foreign Leverage* and repatriations. We do not make a prediction for *U.S. Leverage* because two opposing forces influence its relation with repatriations. *U.S. Leverage* will be positively associated with repatriations if firms distribute funds to service domestic debt. Alternatively, *U.S. Leverage* will be negatively associated with repatriations if domestic debt is used as a substitute for cash from repatriations, or if firms borrow domestically against undistributed foreign earnings.

We include *U.S. Interest Rate*, the interest rate on domestic debt, to control for the domestic cost of borrowing. We anticipate that firms with a higher cost of borrowing in the U.S. have higher repatriations. We include *Foreign Interest Rate*, the interest rate on foreign debt, to control for the foreign cost of borrowing. We expect that firms with a higher cost of borrowing abroad repatriate less. *%Foreign Assets* controls for the size of foreign operations relative to the size of the firm and we expect a positive coefficient on *%Foreign Assets*. We include *U.S. Loss* because Altshuler and Newlon (1993) and Power and Silverstein (2007) find that firms with a domestic net operating loss (NOL) are less likely to repatriate because repatriations convert domestic NOLs into foreign tax credits (FTCs).[19] U.S. MNCs are reluctant to give up the NOL in exchange for an FTC because the FTC has a shorter carryforward period.

Finally, we include four measures to control for country-level factors that affect repatriations. We first determine each country-level measure at the affiliate level, and then we calculate the parent-level score as the average of the affiliate scores. *Mandatory Dividend* equals 1 if the country requires dividends to be paid to shareholders, and 0 otherwise (La Porta et al. 1998). *Corruption* is an index taking values from 1 through 10, with 10 representing the lowest level of corruption (La Porta et al. 1998). Corruption will decrease repatriations if it increases the cost of doing business such that more capital must remain in the country; alternatively corruption may increase repatriations to reduce the probability of expropriation or theft. *Infrastructure* is an index taking values of 1 through 10, with 10 representing the most developed infrastructure (La Porta et al. 1999). All else equal, the less developed a country's infrastructure, the more capital the company likely needs to invest in its operations. Finally, *Capital Control* is equal to 1 if the country restricts a firm's ability to take funds out of the country, and 0 otherwise (International Monetary Fund [IMF] 2006).

---

[19] Repatriation by a firm with a domestic NOL does not incur a repatriation tax because the NOL offsets the taxable income generated by the repatriation. However, because there is no current U.S. tax liability, U.S. tax law does not permit the firm to use any FTC associated with the repatriation, but instead requires it to create a FTC carryforward. Thus, when a firm with a NOL repatriates foreign earnings, ordering rules require it to use some of its NOL and create a FTC carryforward.

V. RESULTS

Descriptive Statistics

Table 2 provides descriptive statistics for our BEA sample. We report all statistics at the firm level unless otherwise noted and show statistics separately for private firms, low PRE public firms (*HighPre* = 0), and high PRE public firms (*HighPre* = 1). We winsorize all continuous measures at the top and bottom 1 percent and truncate all tax rate measures to fall between 0 and 100 percent. Finally, due to confidentiality restrictions, reported medians (Med5) represent the mean of the five middle observations.

Table 2, Panel A reports descriptive statistics for the variables in Equation (1). As expected, public and private firms exhibit several notable differences. Public firms have more extensive foreign operations that are larger overall (mean *Size* equals 13.50 for private firms, 14.74 for low PRE Public firms, and 15.14 for high PRE public firms), and they engage in more sophisticated tax planning (mean *Indirect Ownership* and *Holding Company* are 11.14 and 2.26 for private firms, 19.35 and 5.11 for low PRE public firms, and 24.92 and 7.02 for high PRE public firms). While *Foreign Leverage* is similar across the three subsamples, public firms have significantly higher *U.S. Leverage* than private firms. This difference likely results because, per our definition of *Public*, public firms in our sample can have public debt, while private firms cannot and existing research shows that firms with public debt have, on average, 35 percent more debt than firms with only private debt (Faulkender and Petersen 2006). Our multivariate tests control for these differences across public and private firms.

Within the sample of public firms, approximately 19 percent (506 observations) have *HighPre* equal to 1. Interestingly, *Repatriations* are largest for high PRE firms. The spirit of the Indefinite Reversal Exception, requiring firms to declare that foreign earnings are indefinitely invested abroad, suggests that high PRE firms might exhibit smaller *Repatriations* than other firms. However, *HighPre* is measured as a proportion of assets that are not repatriated. Therefore, high PRE firms can have higher repatriations, on average, but designate a greater proportion of earnings that are not repatriated as PRE. This result could arise if high PRE firms have made more profitable investments that generate more income and, in turn, generate more repatriations. It could also arise if high PRE firms are more likely to borrow in the U.S. using foreign assets as collateral and repatriate more foreign earnings to service U.S. debt. Our interest, however, is in whether high PRE firms are more sensitive to the repatriation tax rate than low PRE firms. As with differences across public and private firms, we control for observable differences across high PRE and low PRE firms. To reduce the possibility that unobservable differences drive our results, we use multiple proxies for reporting incentives and conduct a battery of sensitivity tests.

Table 2, Panel B reports descriptive statistics to compare tax rate measures used in existing research. *DFH Tax Rate* equals the median accounting effective tax rate for all U.S. affiliates operating in a country-year as described in Desai et al. (2001), and *Current FTR* equals current-

*, **, *** (#, ##, ###) Represent significant differences between the high PRE (low PRE) public firms at the 10 percent, 5 percent, and 1 percent two-tailed levels, respectively. This table reports firm attributes using data reported on the BEA Survey Form 10, Form 11, and Form 577 from 1999 to 2004. See Section III for BEA Survey details. Private firms are parent-affiliate groups with privately owned parents as described in the LexisNexis Corporate Affiliations database. Public firms are parent-affiliate groups with parents listed on a U.S. stock exchange. Low PRE public firms are those where the ratio of *PRE/Low Affiliate Assets* < 1 (i.e., *HighPre* $= 0$). High PRE public firms are those where the ratio of *PRE/Low Affiliate Assets* ≥ 1 (i.e., *HighPre* $= 1$). Med5 or Median5 represents the average of the five median observations. We report all statistics at the parent level.
All other variables are defined in Appendix A.

Variable Definitions:
DFH Tax Rate = median of all affiliate tax rates for all U.S. affiliates operating in a country-year as described in Desai et al. (2001);
Current FTR = current-period foreign income taxes paid over foreign pre-tax income for all affiliates in a group;
Creditable Tax Rate = estimates the U.S. parent's creditable taxes upon repatriation estimated as the average of the affiliates' creditable tax rates. The affiliate's creditable tax rate (*Affiliate Creditable Tax Rate*) equals aggregate foreign taxes paid on undistributed foreign earnings from the year the affiliate first enters the BEA sample or 1982, whichever is later, to the current year divided by undistributed pre-tax foreign earnings aggregated over the same period;
U.S. (Foreign) Sales = total domestic (foreign) sales (in millions);
Affiliates = total number of affiliates in a parent-affiliate group;
High Affiliates = total number of affiliates in a parent-affiliate group with *Affiliate Creditable Tax Rate* greater than or equal to 30 percent;
PRE/Low Affiliate Assets = ratio of permanently reinvested earnings reported in the 10-K to total assets in low-tax affiliates;
Affiliate RepDum = proportion of affiliates in a group that pay a dividend to the U.S. parent; and
Parent RepDum = proportion of parents that repatriate from at least one of their foreign affiliates.

period foreign income taxes paid over foreign pre-tax income. Public firms have a lower *DFH Tax Rate* than private firms, consistent with survey evidence in Graham et al. (2011) that the benefit of tax expense deferral is of primary importance in investment location decisions of public companies. Consistent with private firms facing higher income tax burdens and lower expected repatriation tax burdens, *Creditable Tax Rate* is higher for private firms than for both subsamples of public firms. However, *Current FTR* is lowest for private firms. A low *Current FTR* but high *Creditable Tax Rate* suggests that a non-trivial proportion of undistributed earnings were generated in the past when foreign tax rates were relatively higher than the U.S. tax rate. Table 2, Panel C reports general descriptive statistics for the BEA data. Public firms are larger than private firms in terms of number of affiliates and total sales. We control for these differences in our regression analysis.

Capital Market Measures of Reporting Incentives

Table 3, Column (1) reports the results of estimating Equation (1), excluding a measure of *Reporting Incentives*, for our sample of 577 public and private firms with necessary data from 1999 through 2004. Column (1a) reports the marginal effects. Consistent with existing literature, the coefficient on *RepTR* is negative and significant. Table 3, Column (2) reports the results of estimating Equation (1) using *Public* as a proxy for *Reporting Incentives*. The coefficient on *Public* is not significantly different from zero suggesting that, holding the repatriation tax rate constant, public companies are no less likely to repatriate, on average, than private companies. Consistent with H1A, the interaction between *Public* and *RepTR* is negative and significant (–0.0398; $p < 0.10$) suggesting that public firm repatriation is more sensitive to the repatriation tax rate than private firm repatriation.[20]

Table 3, Column (2a) reports the marginal effect of each variable on the unconditional expected value of *Repatriations*, which we use to interpret the coefficient estimates. We calculate the marginal effect of *Public* × *RepTR* using Ai and Norton (2003) and McDonald and Moffitt (1980).[21] The marginal effect of *Public* × *RepTR* on the unconditional expected value of *Repatriations* is –0.0151. This estimate suggests that the change in *Repatriations* when *RepTR* changes from 0 to the sample mean of 0.1115 is 0.168 percent of assets lower for public firms than for private firms. Mean worldwide assets for our sample is \$8.34 billion. Therefore, the average public firm repatriates \$14 million ($-0.0151 \times 0.1115 \times \$8{,}344 = \$14$), or 3.4 percent of foreign earnings less per year than the average private firm. For our 479 public firms, this figure amounts to \$6.7 billion in repatriations per year.

The coefficient on *U.S. ROA* is insignificant while the coefficient on *Foreign ROA* is positive and significant. These results suggest that firms with more profitable foreign operations have more cash available to repatriate and that this effect outweighs the investment opportunity effect predicted by Hartman (1985). However, for *U.S. ROA*, the investment opportunity effect is offset by a lower need for cash. *Size*, *Lag Repatriations*, *U.S. Leverage*, *Foreign Interest*, *%Foreign Assets*, and *Mandatory Dividend* are significant in the expected direction. The positive coefficient on *U.S. Leverage* suggests that firms repatriate foreign earnings, in part, to service domestic debt while the negative coefficient on *Foreign Interest* suggests that firms with a higher cost of borrowing abroad repatriate less, in part, to service foreign debt. We interpret the positive

---

[20] Results in Table 3 and Table 4 are robust to scaling repatriations by worldwide sales or worldwide retained earnings. Results in Table 3 and Table 4, Columns (2) and (3) are also robust to using the log of repatriations as the dependent variable.

[21] A detailed discussion of this calculation is available upon request from the authors. This discussion includes an explanation of the McDonald and Moffitt (1980) decomposition of Tobit coefficients, as well as our STATA code for estimating the marginal effects of interaction terms.

Columns (1), (2), and (3) report coefficients from the Tobit estimation. Columns (1a), (2a), and (3a) report the marginal effect of each variable on the unconditional expected value of *Repatriations*. Details on these calculations are available from the authors. See Appendix A for variable definitions.

coefficient on *%Foreign Assets* as suggesting that firms with proportionately greater foreign assets repatriate a greater proportion of total assets.

Table 3, Column (3) reports the results of estimating Equation (1) for our sample of 479 public firms using *CapMkt* as a proxy for *Reporting Incentives*. This test reduces the possibility that unobservable differences between public and private firms, such as access to capital, affect the sensitivity of repatriation to tax costs, and instead focuses on cross-sectional variation in capital market pressure among public firms. Recall that *CapMkt* equals 1 for public firms for which the *ERC* is in the top quartile of the sample, *BEAT* is in the top quartile, or *DED* is in the bottom quartile, 0 otherwise.[22] Consistent with H2, the interaction between *CapMkt* and *RepTR* is negative and significant (–0.0350; $p < 0.05$) suggesting that repatriation by public firms with a potentially larger stock price response to the repatriation tax expense is more sensitive to the repatriation tax rate relative to repatriation by other public firms. Inferences are similar if we test each condition separately, although only significant for two of the three conditions. If we define *CapMkt* as equal to 1 for firms in the top quartile of *ERC*, then the coefficient on *CapMkt* × *RepTR* is –0.0436 (standard error = 0.0174). If we define *CapMkt* as equal to 1 when *BEAT* is in the top quartile, then the coefficient on *CapMkt* × *RepTR* is –0.0338 (standard error = 0.0174). If we define *CapMkt* as equal to 1 if *DED* is in the bottom quartile, then the coefficient on *CapMkt* × *RepTR* is –0.0146 (standard error = 0.0149).[23]

The marginal effect of *CapMkt* × *RepTR* on the unconditional expected value of *Repatriations* is –0.0123. Mean worldwide assets for our public sample is $9.62 billion. Thus, the change in *Repatriations* when *RepTR* changes from 0 to the sample mean of 0.1133 is 0.139 percent of assets (–0.0123 × 0.1133) or $13.4 million (–0.0123 × 0.1133 × $9,616 = $13.4), or 2.8 percent of public firm foreign earnings lower for a firm with high capital market pressure than for a firm with low capital market pressure. This figure amounts to approximately $2.9 billion per year for our 1,298 high capital market pressure observations (($13.4 × 1,298)/6). In addition, the marginal effect of

---

[22] Mean (median) *ERC* in our sample is 4.06 (2.67) with a standard deviation of 5.19. The mean (median) of *BEAT* is 23.5 percent (21.1 percent) with a standard deviation of 18.2 percent. The mean (median) of *DED* is 4.5 percent (0 percent) with a standard deviation of 7.4 percent. *CapMkt* equals 1 for 1,298 of the 2,655 observations in the sample of public firms.

[23] We also examine the robustness of these results to using different measures of *BEAT* to define *CapMkt*. Results are consistent when we define *BEAT* using three cents as a cutoff instead of one cent, using last year's earnings instead of analyst forecasts and both one cent and three cent cutoffs, and using annual instead of quarterly earnings. Results are also consistent if we define *BEAT* as equal to 1 if the number of consecutive years the firm met analyst forecasts by one cent or less, with a maximum of 5 years, is in the top quartile, similar to Barth et al. (1999). These measures also produce consistent results when we test them separately, except when we use last year's earnings as the benchmark with a three cent cutoff.

Public × *RepTR* is larger than the marginal effect of *RepTR* (–0.0080), consistent with MNCs placing at least as much importance on expense deferral relative to cash tax deferral and with the results in Graham et al. (2011).

Earnings Measures of Reporting Incentives

Table 4 reports the results of estimating Equation (1) for our sample of 479 public firms using *HighPre* as our measure of *Reporting Incentives*. *HighPre* × *RepTR* tests for the effect of reporting incentives on repatriation by examining whether repatriation by public firms that defer recognition of the repatriation tax expense is more sensitive to the repatriation tax rate relative to repatriation by other public firms. Consistent with H3, the coefficient on *HighPre* × *RepTR* is negative and significant (–0.0417; $p < 0.05$).[24] In Column (1a) we report the marginal effects. The marginal effect of *HighPre* × *RepTR* on the unconditional expected value of *Repatriations* is –0.0160. Thus, the change in *Repatriations* when *RepTR* changes from 0 to the sample mean of 0.1133 is 0.181 percent of assets (–0.0160 × 0.1133) or \$17.4 million (–0.0160 × 0.1133 × \$9,616 = \$17.4), or 3.6 percent of public firm foreign earnings lower for a high PRE public firm than for a low PRE public firm. This figure amounts to approximately \$1.5 billion per year for our 506 high PRE observations ((\$17.4 × 506)/6).

Collectively, our empirical results tell a consistent story in which reporting incentives deter repatriation. First, repatriation by public firms appears to be more sensitive to the repatriation tax rate than repatriation by private firms because public firms place relatively greater focus on accounting earnings. Second, repatriation by public firms that anticipate a more negative stock price reaction to the repatriation tax expense is more sensitive to the repatriation tax rate than repatriation by other public firms. Third, repatriation by public companies that rely extensively on PRE is more sensitive to the repatriation tax rate than repatriation by other public firms.[25]

VI. SUPPLEMENTAL ANALYSES

Firms with High PRE and High Capital Market Pressure

As discussed in Section IV, if public firms engage in different types and amounts of tax planning than private firms and/or high PRE firms engage in different types and amounts of tax planning than low PRE firms, then a self-selection problem could bias the coefficients on *Public* × *RepTR* or *HighPre* × *RepTR* up or down depending on the relationship between these tax-planning differences and repatriations. To control for this potential bias, we include *Indirect*

---

[24] We evaluate the sensitivity of this result using many definitions of *HighPre*. Results are similar when we define *HighPre* as equal to 1 when PRE meets the following conditions in a benchmark year (1999 or 2004): the firm's ratio of PRE to total assets in low-tax affiliates is greater than or equal to 95 percent or 80 percent, the ratio of PRE to retained earnings in low-tax affiliates is greater than or equal to 1, 95 percent, or 80 percent, PRE divided by total foreign assets, worldwide assets, or worldwide retained earnings is greater than or equal to the 90th percentile (we use the 90th percentile for these scalars because this ratio is greater than 1 for only a few observations). We also evaluate the use of a continuous measure. Results are similar when we define *HighPre* as PRE divided by assets in low-tax affiliates, but are not significant when we define *HighPre* as PRE divided by total foreign assets ($t = -1.54$).

[25] An alternate interpretation of the negative coefficient on *HighPre* × *RepTR* is that high PRE firms lack the ability to repatriate because they are more heavily invested in operating assets abroad than other firms. We formally rule out this explanation in the "Foreign Cash Holdings" section by showing that, relative to other public firms, the cash holdings of high PRE firms increase more when the repatriation tax rate increases.

Columns (1), (2), and (3) report coefficients from the Tobit estimation. Columns (1a), (2a), and (3a) report the marginal effect of each variable on the unconditional expected value of *Repatriations*. Details on these calculations are available from the authors. See Appendix A for variable definitions.

Ownership and *Holding Company* as control variables and run sensitivity tests using several other measures of tax-planning activity.[26] To further rule out this possibility, we investigate whether the higher sensitivity of repatriation to the repatriation tax rate for high PRE firms ($HighPre = 1$) is concentrated in firms facing greater capital market pressure ($CapMkt = 1$). We report these results in Table 4, Columns (2) and (3). Consistent with the earnings consequences of repatriation acting as a greater deterrent to repatriation in the presence of high capital market pressure, the interaction term, $HighPre \times RepTR$, is negative and significant for firms with $CapMkt = 1$ but is insignificant for firms with $CapMkt = 0$.[27,28]

Foreign Cash Holdings

Next, we evaluate the association between the unrecognized expense for repatriation taxes and foreign cash holdings for the public firms in our sample. Although we conjecture that reporting incentives lead to predictable differences in repatriation across high and low PRE firms, our results could still be attributable to varying investment opportunities. A public firm that designates earnings as PRE is declaring its intention to reinvest foreign earnings abroad indefinitely and may, as a result of investment opportunities, be more sensitive to the repatriation tax rate. To control for this possibility, we include measures of foreign and domestic after-tax return on assets in our main empirical tests. As a sensitivity test, we replace measures of foreign and domestic return on assets with proxies for anticipated domestic and foreign growth opportunities. To further rule out the possibility that our results are confounded by differences in investment opportunities, we follow Foley et al. (2007) and investigate the effect of tax expense deferral on foreign cash holdings.

---

[26] Results are robust to using measures of tax aggressiveness from existing literature. Specifically, results are unchanged when we include a tax shelter score from Wilson (2009) or Lisowsky (2010). A tax shelter score is the predicted probability that a firm is engaging in a tax shelter, conditional on a set of firm characteristics. Those firm characteristics and the coefficients are documented by Wilson (2009) and Lisowsky (2010), who use samples of tax shelter participants to develop their models. Results are also unchanged when we include the percent of affiliates located in tax havens as a measure of tax aggressiveness, where tax havens are defined as in Hines and Rice (1994). In addition, the coefficients on each of these alternative measures are insignificant.

[27] Results are similar if we evaluate each condition used to define *CapMkt* separately. However, in these tests we use medians rather than quartiles to define each condition to create relatively equal sample sizes. When we define partitions based on the median of *ERC*, the coefficient on $HighPre \times RepTR$ is -0.0426 ($t = -1.92$) for observations above the median and -0.0382 ($t = -1.28$) for observations below the median. The coefficient on $HighPre \times RepTR$ is -0.0515 ($t = -2.48$) for observations with *BEAT* above the median and -0.0005 ($t = -0.02$) for observations with *BEAT* below the median. The coefficient on $HighPre \times RepTR$ is -0.0697 ($t = -2.13$) for observations with *DED* below the median and -0.0305 ($t = -1.27$) for observations with *DED* above the median.

[28] We avoid using a three-way interaction term because of the problems of interpreting such an effect in a Tobit model (Ai and Norton 2003).

Foley et al. (2007) find that repatriation taxes help explain the build-up of cash abroad and, more specifically, in affiliates located in low-tax jurisdictions. If an MNC designates foreign earnings as PRE because they are invested in profitable activities, then *HighPre* will have either a negative or insignificant effect on the association between the repatriation tax rate and foreign cash holdings because these profitable investments are not reflected in the cash account. However, to the extent that public companies designate foreign earnings as PRE because of the earnings effect of repatriations, we expect that these consequences will result in more cash held abroad, i.e., they will exacerbate the positive relation between the repatriation tax rate and foreign cash holdings.

To investigate this conjecture we estimate the following empirical model, which closely follows Foley et al. (2007), using ordinary least squares (OLS):[29]

$$\begin{aligned}LN(Cash/Net\,Assets) = {} & \beta_0 + \beta_1 RepTR + \beta_2 HighPre + \beta_3 HighPre \times RepTR \\ & + \sum \beta_k Controls_k + \sum \beta_t Year_t + \sum \beta_j Industry_j + \varepsilon. \qquad (2)\end{aligned}$$

LN(Cash/Net Assets) is the natural log of foreign cash holdings divided by non-cash worldwide assets consistent with Foley et al. (2007). *Foreign Investment* is foreign R&D plus foreign capital expenditures divided by worldwide assets. All other variables are defined as in Equation (1). We include *Foreign ROA* to control for investment opportunities abroad. As investment opportunities increase, we expect firms to hold less cash because the cash will be invested in productive assets. However, the precautionary motive to hold cash suggests that firms with better investment opportunities will hold more cash to ensure that they do not miss out on profitable investment opportunities due to adverse shocks (Opler et al. 1999). We include *U.S. ROA* to control for investment opportunities in the United States. We expect a negative coefficient if firms are more likely to repatriate when U.S. profitability increases and a positive coefficient if firms are less likely to repatriate when domestic operations are generating more cash. *Size* controls for the transaction motive to hold cash, which predicts that, since there are economies of scale when converting non-cash assets into cash, large firms hold less cash (Baumol 1952; Miller and Orr 1966). *Foreign Leverage* controls for the need to use cash to meet debt obligations and we expect a negative coefficient. *Foreign Investment* controls for the use of cash to invest in capital assets and research and development. We expect a negative coefficient to the extent that these investments consume cash and a positive coefficient to the extent that this variable proxies for growth opportunities (Bates et al. 2009). All other variables control for the effect of repatriations on cash, thus predictions are opposite those in Equation (1).

We report the results of estimating Equation (2) for our sample of public firms in Table 5. We expect and find that the coefficient on *HighPre* × *RepTR* is positive and significant.[30] This result is consistent with the view that undistributed foreign earnings are trapped abroad for firms with stronger reporting incentives and helps rule out the possibility that the results in Table 4 stem from higher investment opportunities abroad for high PRE firms. The insignificant coefficient on *Foreign ROA* suggests that the investment effect and precautionary motive offset one another. The positive

---

[29] We use OLS to be consistent with Foley et al. (2007) and because it is not feasible that cash balances are negative, making Tobit inappropriate.

[30] This result is robust when we replace *Foreign ROA* and *U.S. ROA* with measures of foreign growth opportunities (three-year historical foreign sales growth by country and industry and weighted by affiliate assets in the affiliates country and industry) and domestic growth opportunities (three-year historical domestic sales growth by industry), respectively.

Robust standard errors from OLS regressions are reported in parentheses.

LN(Cash/Net Assets) is the natural log of foreign cash divided by non-cash worldwide assets. *Foreign Investment* is foreign capital expenditures plus foreign R&D divided by worldwide assets. See Appendix A for definitions of all other variables.

coefficient on *U.S. ROA* in Column (2) suggests that domestically profitable firms' lower need for cash in the U.S. outweighs the investment effect, but only after including the full set of control variables. The negative coefficient on *Size* in Column (1) is consistent with the transaction motive to hold cash. However, this effect becomes insignificant in Column (2). The positive coefficient on *Foreign Investment* suggests that this variable is a proxy for growth opportunities and is consistent with existing research that finds that firms with better investment opportunities hold more cash (Opler et al. 1999).

VII. CONCLUSION

U.S. international tax policy plays a role in the ability of U.S. multinationals (MNCs) to compete in the global marketplace and various opponents of current tax policy argue that it creates incentives for U.S. firms to park foreign affiliate profits in low-tax countries, thereby reducing domestic investment. These incentives arise because MNCs incur a tax cost upon repatriation of foreign affiliate earnings generally equal to the difference between the U.S. tax rate and the average foreign tax rate paid on the repatriated earnings. A factor that has received little attention in the empirical literature on repatriation behavior is that the accounting for repatriation taxes can also affect repatriation decisions.

Financial reporting rules allow firms to delay recognition of a repatriation tax expense in the period in which the firm generates the earnings by designating them as permanently reinvested earnings (PRE) under the Indefinite Reversal Exception. Instead, the firm recognizes any unrecognized repatriation tax expense in the period that it repatriates those earnings. Firms that face reporting incentives to consistently report strong earnings numbers have an incentive to delay repatriation to avoid recognizing a repatriation tax expense in the financial statements.

We find that reporting incentives deter repatriations. Specifically, we find that repatriation by public firms is more sensitive to the repatriation tax rate than repatriation by private firms. In a sample of only public firms, we find that repatriation by firms with a high price-sensitivity to earnings and/or by firms that make extensive use of the PRE designation such that they would recognize a larger repatriation tax expense upon repatriation are more sensitive to the repatriation tax rate than repatriation by other firms. Our findings are relevant for both tax policy makers and accounting standard-setters because they suggest that the current financial reporting rules for the U.S. tax on foreign affiliate earnings deter repatriation and contribute to the nearly $1 trillion MNCs have parked outside the United States. In light of recent debates regarding the merits of the U.S. system of worldwide taxation with deferral and its contribution to the pool of funds overseas, our results suggest that merely eliminating deferral of income tax expense recognition could significantly reduce incentives to park profits outside the U.S. without eliminating deferral of income tax payments. However, as net income is often relied upon by market participants to evaluate firm performance, the elimination of the Indefinite Reversal Exception could adversely affect U.S. firms' international capital market competiveness.

APPENDIX A

REGRESSION VARIABLES

Variable Name, Definition, and Source (BEA unless otherwise noted)

Dependent Variables

Repatriations = current-year repatriations scaled by worldwide assets.

Variables of Interest

Reporting Incentives:

H1A: *Public* = 1 if the firm has publicly traded equity, 0 otherwise;

H1B: *CapMkt* = 1 if the firm's *ERC* is in the top quartile of the sample, *BEAT* is in the top quartile, or *DED* is in the bottom quartile, 0 otherwise; and

H2: *HighPre* = 1 if the firm's ratio of permanently reinvested earnings divided by total assets in low-tax affiliates ≥ 1 in a benchmark year (1999 or 2004), 0 otherwise. Low-tax affiliates are those with *Affiliate Creditable Tax Rate* ≤ 30 percent.

ERC = firm's long-window *ERC* estimated by regressing 16-month cumulative abnormal returns on the change in annual earnings, excluding extraordinary items and discontinued operations, scaled by the market value of equity at the beginning of the year;

BEAT = proportion of quarters that the firm appears in I/B/E/S for which it beat the median analyst EPS forecast by 1 cent or less. We estimate *BEAT* beginning in the first year the firm appears in I/B/E/S or 1984, whichever is later, and ending in the current year;

DED = proportion of the firm's stock owned by long-term institutional investors (i.e., dedicated investors) as defined by Bushee (1998);

RepTR = our estimate of the rate of tax the firm would owe to the U.S. if it repatriated all undistributed foreign earnings, computed as the U.S. statutory rate (35 percent) minus *Creditable Tax Rate*;

Affiliate Creditable Tax Rate = for each year, we subtract dividends paid (repatriations) from pre-tax income to obtain an estimate of each affiliate's undistributed pre-tax income at the end of each year. We aggregate each affiliate's tax expense and undistributed pre-tax income over time beginning with the date the affiliate is first included in the BEA survey or 1982 (the first BEA survey), whichever comes last, and ending at the end of year *t*–1. This process results in an estimate of each affiliate's cumulative taxes paid on undistributed pre-tax income (CTP) and cumulative undistributed pre-tax income (CUPTI). *Affiliate Creditable Tax Rate* for year *t* equals year *t*–1 CTP divided by year *t*–1 CUPTI; and

Creditable Tax Rate = estimate of the ratio of an MNC's foreign tax credit to its pre-tax dividend if all undistributed earnings were repatriated. An MNC's year *t Creditable Tax Rate* equals the ratio of year *t*–1 CTP summed across all of its affiliates to year *t*–1 CUPTI summed across all of its affiliates.

Control Variables

Foreign ROA = foreign net income scaled by foreign assets;

U.S. ROA = domestic net income scaled by domestic assets;

Size = natural log of foreign sales;

Lag Repatriations = prior-year repatriations scaled by prior-year worldwide assets;

Indirect Ownership = ratio of indirectly owned affiliates to total affiliates;

Holding Company = ratio of holding company affiliates (NAICS code 5512) to total affiliates;

U.S. Leverage = ratio of domestic short-term and long-term debt to domestic assets;

Foreign Leverage = ratio of foreign short-term and long-term debt to foreign assets;

U.S. Interest Rate = ratio of domestic interest paid on domestic short-term and long-term debt;

Foreign Interest Rate = ratio of foreign interest paid divided by foreign short-term and long-term debt;

%Foreign Assets = ratio of foreign assets to worldwide assets;

U.S. Loss = 1 if the U.S. parent reports a domestic pre-tax loss in the current year, 0 otherwise;

Mandatory Dividend = country-level indicator variable equal to 1 if the country requires that dividends are paid to shareholders, 0 otherwise, weighted by the number of affiliates in each type of country (La Porta et al. 1998), available at: http://www.economics.harvard.edu/faculty/shleifer/dataset;

Corruption = country-level variable ranging from 1 to 10 indicating high and low corruption, respectively, weighted by the number of affiliates in each type of country (La Porta et al. 1999), available at: http://www.economics.harvard.edu/faculty/shleifer/dataset;

Infrastructure = country-level variable ranging from 1 to 10 indicating low and high quality infrastructure, respectively, weighted by the number of affiliates in each type of country (La Porta et al. 1999), available at: http://www.economics.harvard.edu/faculty/shleifer/dataset; and

Capital Control = country-level indicator variable equal to 1 if the country restricts firms' ability to take funds out of the country, 0 otherwise, weighted by the number of affiliates in each type of country (IMF 2006).

ABSTRACT: This paper examines the impact of hedge fund activism on corporate tax avoidance. We find that relative to matched control firms, businesses targeted by hedge fund activists exhibit lower tax avoidance levels prior to hedge fund intervention, but experience increases in tax avoidance after the intervention. Moreover, findings suggest that the increase in tax avoidance is greater when activists have a successful track record of implementing tax changes and possess tax interest or knowledge as indicated by their Securities and Exchange Commission (SEC) 13D filings. We also find that these greater tax savings do not appear to result from an increased use of high-risk and potentially illegal tax strategies, such as sheltering. Taken together, the results suggest that shareholder monitoring of firms, in the form of hedge fund activism, improves tax efficiency.

I. INTRODUCTION

Ownership structure is an important, but under-studied, determinant of corporate tax policies (Shackelford and Shevlin 2001). Only recently have a few studies started to explore this area (e.g., Badertscher et al. 2010a, 2010b; Chen et al. 2010). This paper extends the literature by examining the role of hedge fund activists on the levels of corporate tax avoidance. Hedge fund activists have been playing an increasingly important role in capital markets and prompting profound changes in the way the corporate world operates (Kahan and Rock 2007; Brav et al. 2008, 2010; Klein and Zur 2009).[1] In this paper, we investigate whether this important and unique class of shareholders has any impact on corporate tax-planning efficiency.

There is significant variation in the level of corporate tax avoidance across publicly traded firms (e.g., Dyreng et al. 2008). While some of this variation is attributable to size and industry factors, a significant portion remains unexplained. One potential source for the unexplained variation could be due to differences in firm managers' incentives for tax planning. That is, managers' preference to limit the effort and risk associated with tax planning might contribute to the observed low levels of tax avoidance for some firms. Hedge fund activists can provide informed monitoring by pushing effort-averse firm managers to improve tax-planning efficiency. Hedge fund activists also tend to have concentrated investment portfolios, and the performance of an individual firm may significantly impact their portfolio returns (Kahan and Rock 2007; Brav et al. 2008). As a result, hedge fund activists have an incentive to exercise their influence to encourage individual firms to employ tax avoidance strategies that enhance after-tax cash flows and firm value.

Anecdotal evidence suggests that firms targeted by hedge funds tend to be tax inefficient, and activist hedge funds often demand efficiency improvements in tax and other areas from these target firms. For instance, in 2007, the hedge fund Third Point LLC targeted PDL Biopharma Inc., aiming to change the firm's business strategies and to remove its CEO, Mark McDade. When making its case to the board of directors, Third Point wrote: "Mr. McDade lacks the ability to communicate with the investment community effectively in part because he has a poor understanding of even basic financial concepts . . . He readily admitted to us that he has not properly thought through nor effectively utilized PDL's tax credits, which has and will result in reduced value for PDL shareholders." Calling the unused tax credits a "readily exploitable Company asset," Third Point identifies the firm's tax strategy as a potential source of value improvement. In another example, in October 2007, hedge fund activist Sandell Asset Management Corp. recommended to the target firm, Sybase Inc., that improving tax efficiency would provide opportunities for value creation. Specifically, the hedge fund activist stated that, "Given the company's stable base of maintenance revenue, a moderate level of leverage is more tax efficient and will improve returns on equity."[2]

---

[1] This literature finds that hedge fund activists are successful in eliciting positive changes in target firms' corporate governance, business policies, and financial performance. For instance, prior studies document increases in dividend payout, CEO turnover, pay-for-performance sensitivity, and board representation in the target firms after hedge fund interventions. Please refer to Brav et al. (2010) for a detailed review.

[2] For details of these two examples, please refer to http://www.sec.gov/Archives/edgar/data/882104/000089140-07-001301.txt, and http://www.sec.gov/Archives/edgar/data/768262/000101359407000460/sybase13dppt-101207.htm. More examples are provided in Appendix A, in which hedge fund activists proposed to increase tax efficiency through strategies such as taking advantage of loss carryforwards, engaging in tax-efficient spin-offs, and adopting tax-beneficial organizational structures. However, hedge fund activists typically do not publicly discuss tax issues, probably due to the opaque nature and legal concerns of tax avoidance. In Section IV, we report that some activists exhibit interest and knowledge in tax planning in their public 13D filings. Furthermore, the results in Table 6 show that these activists have a greater impact on tax avoidance than other activists, even though firms targeted by both groups of activists experience significant increases in tax avoidance.

In this study, we collect a large sample of 2,981 hedge fund activist events from 1994 to 2008, using a hedge fund's filing of Schedule 13D as the initiation of hedge fund activism (Brav et al. 2008; Greenwood and Schor 2009; Klein and Zur 2009). We define tax avoidance as activities that reduce explicit taxes per dollar of pretax accounting earnings (Hanlon and Heitzman 2010), and infer a target firm's tax avoidance level from four commonly used metrics.[3] The first two metrics, based on effective tax rates (ETR), are measured as a firm's income tax expense and cash taxes paid scaled by pretax income, respectively. The other two measures reflect differences between a firm's reported income and taxable income (book-tax difference, or BTD.) They are the Manzon-Plesko (2002) book-tax difference, and a derivative BTD measure proposed by Desai and Dharmapala (2006) to capture differences resulting mainly from tax planning. To control for the endogeneity of hedge funds' targeting decisions and market-wide changes in tax avoidance, we follow prior studies (e.g., Li and Prabhala 2007; Lawrence et al. 2011) and use the propensity score matching method to construct a sample of control firms. The propensity score is the predicted probability of becoming a hedge fund activism target in the next year, estimated from a logistic regression model as in Brav et al. (2008). We adjust the values of all variables used in the analysis by subtracting the corresponding value for the matched firm from that for the sample firm, and use the differences for our empirical analysis. In the baseline analysis, we find that target firms have lower tax avoidance levels than control firms before hedge fund intervention. We also find that target firms experience increases in tax avoidance after the fund intervention compared with the matched control firms.

Because hedge fund interventions are often associated with profound and multi-dimensional effects on target firms (Brav et al. 2010), it is possible that indirect effects, arising from changes in other tax determinants such as operating, financing, and investment activities, drive the observed changes in tax avoidance. To isolate direct effects of hedge fund activists on corporate tax avoidance, we conduct several tests to adjust for such indirect effects. First, we construct various control samples matched on changes in operating, financing, and investment activities, and find these control samples do not experience similar increases in tax avoidance as target firms. Second, we employ a multivariate regression approach, which explicitly controls for other determinants of tax avoidance that may give rise to the indirect effects. We continue to find consistent results. Finally, we find that increases in tax avoidance in target firms depend on the associated hedge funds' past success in implementing tax changes. In addition, we create proxies for fund activists' interest in, and knowledge of, tax issues from their SEC filings. Using these proxies, we document a link between such fund characteristics and changes in target firms' tax avoidance.

We also conduct several additional analyses. Extending the event window, we find that increases in tax avoidance for target firms do not reverse over the five-year period after the intervention, consistent with hedge fund activists inducing at least intermediate-term changes in firms' tax strategies. Further, we analyze whether target firms' increased tax avoidance is associated with an increased use of high-risk and potentially illegal tax-planning strategies (e.g., tax sheltering). Using sheltering estimates from Wilson's (2009) and Lisowsky's (2010) sheltering models, we find no evidence that target firms are more likely to engage in tax sheltering after hedge fund intervention.

An alternative explanation for our results is that hedge fund activists could just be cherry-picking target firms that are already improving their tax avoidance. To address this concern, we conduct trend analyses and find that, on average, the target firms were experiencing a decreasing trend in tax avoidance prior to the activist event, while control firms do not exhibit this pattern.

---

[3] To avoid the complexity of determining the legality or appropriateness of the mechanism used to reduce the tax burden, we follow the literature (e.g., Chen et al. 2010; Frank et al. 2009; Hanlon and Heitzman 2010) and define tax avoidance as a broad description of tax strategies that reduce taxes relative to book income, rather than a narrower construct such as tax evasion.

Collectively, our results suggest that the observed increases in target firms' tax avoidance levels are partially attributable to the direct effects of hedge fund activists on target firms' tax planning.

Our paper makes several contributions. First, we contribute to the growing literature on the effect of ownership structure on corporate tax avoidance. To the best of our knowledge, our paper is the first to document that hedge fund activists induce increases in target firms' tax avoidance. Second, we contribute to the current literature on the effect of hedge fund activists on target firms. Specifically, we find that the increases in tax avoidance are related to hedge fund characteristics (e.g., their past success, interest, and knowledge in target firms' tax planning), and there is no evidence of tax sheltering. These findings suggest that hedge funds' informed monitoring is associated with improvements in target firms' tax efficiencies, which increase both cash flows and firm value.[4]

The remainder of the paper is organized as follows. Section II reviews the related literature and develops the hypotheses. Section III discusses the sample and variable measurement. Section IV presents the primary results of the study, while Section V reports additional tests and the sensitivity of the results to alternative tests and specifications. Section VI concludes.

II. LITERATURE REVIEW AND HYPOTHESIS DEVELOPMENT

A number of recent papers identify hedge fund activism as an effective influence on shareholder monitoring by providing evidence of post-intervention improvements in governance structure, capital structure, and operational decisions. Brav et al. (2008) find that hedge funds are successful in mitigating agency costs and improving firm value. Target firms in their sample experience increases in payout, higher rates of CEO turnover, and improvements in operating performance and corporate governance.[5] Similarly, Klein and Zur (2009) report that hedge fund activists are successful in pressing target firms to repurchase stock, replace CEOs, and increase board representation of the funds. Bratton (2006), Briggs (2007), and Clifford (2008) show that hedge fund activists improve their target firms' short-term and long-term performance. Greenwood and Schor (2009), on the other hand, attribute positive returns of target firms to hedge funds' ability to force target firms into a takeover.[6]

Building upon this literature, we argue that hedge fund activists have the incentive and the ability to influence their target firms' tax avoidance activities. First, compared with other institutions, hedge fund activists have stronger incentive to engage in costly monitoring activities, since they are less susceptible to the free-rider problem and fund managers have stronger compensation incentives. Hedge funds are largely unregulated and are not subject to the "prudent man" rule, allowing them to accumulate a large stake in an individual company (Clifford 2008). As a result, hedge funds have incentive to undertake monitoring activities to improve the operational performance of target firms, so that their marginal returns from the improved firm governance and performance exceed their monitoring costs. In addition, hedge fund managers' pay depends largely on their funds' absolute returns (Kahan and Rock 2007). A hedge fund can invest a large proportion of its wealth in individual firms and has incentives to influence individual firms' operations, such as reducing tax payments, to generate improved returns.

---

[4] In untabulated results, we find that the increase in tax avoidance following the intervention is positively associated with an increase in targets' valuation, as measured by Tobin's Q and abnormal returns.

[5] Brav et al. (2008) also argue that hedge fund activists are not short-term focused. Such funds have an average holding period of about 20 months, and their positive impact on the target firm does not fully dissipate even after the fund's exit.

[6] Most of these studies suggest that positive market returns are due to fundamental improvements in firm practices elicited by hedge fund intervention. To the best of our knowledge, Greenwood and Schor (2009) is the only paper that attributes the documented positive returns of target firms to the ability of hedge funds to involve target firms as objects of takeover activity.

Second, increases in tax avoidance can help hedge funds to achieve their goal of improving firm value. One important source of gains from intervention comes from the economic benefits of constraining inefficient managerial actions (Maug 1998; Gillan and Starks 2000). Tax avoidance increases firm value by generating tax savings that potentially improve accounting earnings and cash flows (Hanlon and Heitzman 2010), which should benefit hedge fund activists and increase the value of their investments. With statutory tax rates often in excess of one-third of a company's profits, tax avoidance provides a significant opportunity for hedge fund activists to increase free cash flow, firm value, and the value of their investments.[7]

Hedge fund activists also have the ability to push for more efficient tax management through their enhanced monitoring. They can set "the tone at the top," analogous to the effect of top managers on tax avoidance (Dyreng et al. 2010), by emphasizing the importance of tax planning to the target firm. In addition, prior literature finds that hedge funds achieve significant success in promoting corporate changes (Brav et al. 2008; Klein and Zur 2009). Hedge funds have relatively high percentages of ownership and can use leverage and derivative instruments to obtain beneficial ownerships or voting rights (Hu and Black 2006). They can exercise their shareholder rights to nominate and elect board members, sponsor shareholder proposals, and launch proxy fights (Bratton 2006; Briggs 2007; Klein and Zur 2009). They also frequently use public media to push for corporate changes, and cooperate with other institutional investors to make their interventions successful (Brav et al. 2008). Therefore, managers of target firms have incentives to meet hedge funds' demands for more efficient tax planning. In summary, hedge fund activists' strengthened monitoring of effort-averse firm managers could improve target firms' tax planning.

Anecdotal evidence supports this perspective. When targeting BNS Co. in 2002, hedge fund Hummingbird Management, LLC stated:[8]

> Our motivation is purely financial; we only seek to maximize returns from our investment. The important goals are to maximize returns on remaining assets while minimizing taxes and ongoing costs, thereby maximizing the ultimate cash payment, to the owners of the company. (*Hummingbird vs. BNS Co.* 2002)

This activist statement is consistent with hedge fund activists' intent to improve tax planning to increase firm value. In this filing, Hummingbird also proposes the following specific change in tax strategies, exhibiting its knowledge and interest in tax planning:

> We feel that efforts should be made to fully utilize the company's NOL (net operating loss). Using the NOL to shield income thrown off from the building and from the proceeds from asset sales would minimize tax expense to the company.

We provide additional anecdotal evidence that activist funds recognize the importance of target firm tax strategy in Appendix A. Based on the above discussions regarding hedge funds activists' incentive and ability to influence their target firms' tax avoidance activities, we propose the following hypothesis:

---

[7] Assuming that tax planning generates economic benefits, one might ask why target firm managers do not always engage in such planning. There are frictions that could induce inefficiency in tax planning of our target firms. For example, prior literature suggests that target firm managers lack adequate incentive to maximize firm value (e.g., Brav et al. 2008; Klein and Zur 2009). Target firms may underinvest in tax planning even though it is value-enhancing. Hedge fund activism can help alleviate this friction. Brav et al. (2008) find hedge fund activism increases pay-for-performance sensitivities for corporate executives, providing stronger incentives for effort-averse managers to improve tax planning (Hanlon 2005).

[8] See: http://www.sec.gov/Archives/edgar/data/14637/0001164073-02-000022.txt

Hypothesis: Firms targeted in hedge fund activism exhibit higher levels of tax avoidance after the activist event.

III. DATA AND VARIABLE CONSTRUCTION

Sample Selection

Consistent with prior literature (e.g., Brav et al. 2008; Klein and Zur 2009), we construct our hedge fund sample from Schedule 13D filings. The 1934 Securities Exchange Act requires investors who acquire a 5 percent or greater stake in a publicly traded firm to file a Schedule 13D with the SEC within ten days and declare any intentions to influence the firm's management.[9] In addition, these investors should use Schedule 13D/A to report material changes in a held position.

We start our sample collection by obtaining all Schedule 13D and 13D/A filings between January 1, 1994, and December 31, 2008, from the EDGAR database of the SEC. We start from 1994 because company filings in the SEC EDGAR database were sporadic before 1994 (SEC 2006). In addition, the use of a post-1993 sample ensures the consistency in the accounting treatments for income taxes for our sample period due to the issuance of FAS 109, effective in 1993. From each filing, we collect the filing date, the name of the filer, and the name of the identified target. The filers are then matched with a comprehensive list of hedge funds to identify Schedule 13D and 13D/A filings by hedge funds.[10] Our sample includes 435 activist hedge funds and 2,981 activist events in the period 1994–2008.

Table 1, Panel A, shows the distribution of hedge fund activist events by year. There is an increasing trend in the number of hedge fund activist events over time. In Panel B, we present the frequency of participation by hedge funds. A majority (60.69 percent) of funds are involved in no more than three activist events in the sample period, while 14.94 percent engage in more than ten activist events in the period. This result suggests that while the majority of hedge funds do not engage in activism on a regular basis, some do so frequently. In Panel C, we show the industry distribution of the target firms based on two-digit SIC industry classification. Prior literature finds cross-industry variation in firms' effective tax rates, suggesting that industry differences may partially explain differences in levels of tax avoidance among firms. Therefore, we include industry dummies in each of our primary tests to control for industry effects. In the empirical analysis, we exclude target firms in financial and utility industries since they have unique accounting requirements and regulatory environments (Hanlon 2005).

Variable Construction

In addition to hedge fund activism data, we obtain the required financial statement data from Compustat, institutional ownership data from Thomson's 13F database, and daily stock return data from CRSP. Appendix B provides a detailed definition of each variable used in our empirical analysis. Hanlon and Heitzman (2010) call for caution with respect to the selection of tax avoidance measures. In particular, they note that different empirical metrics computed from the financial statements capture different aspects of a firm's tax strategy. Certain empirical measures do not consistently reflect the impact of tax strategies that permanently reduce tax liability (e.g., debt tax shields) versus other strategies that simply defer taxes to future periods (e.g., accelerated

---

[9] When the investor has no intention to influence firm management, she should file Schedule 13G instead of 13D.

[10] We are grateful to Wei Jiang for sharing the list of 236 hedge fund activists used in Brav et al. (2008). We also thank Fei Pan for sharing a list of hedge funds collected from four hedge fund databases: Tremont Advisory Shareholder Services (TASS), HedgeFund.Net (HFN), Center for International Securities and Derivatives Markets (CISDM), and HedgeFund Intelligence.

TABLE 1

Descriptive Statistics for the Hedge Fund Activism Sample

Panel A: Number of Hedge Fund Activist Events by Year of First SC 13D Filing

Year	Frequency	Percent
1994	12	0.40
1995	40	1.34
1996	109	3.66
1997	224	7.51
1998	169	5.67
1999	151	5.07
2000	168	5.64
2001	147	4.93
2002	154	5.17
2003	194	6.51
2004	221	7.41
2005	346	11.61
2006	373	12.51
2007	384	12.88
2008	289	9.69
Total	2,981	100

Panel B: Participation Frequency of Hedge Fund Activists

Number of Events	Number of Activists	Percent
1	150	34.48
2	72	16.55
3	42	9.66
4	22	5.06
5	22	5.06
6	18	4.14
7	16	3.68
8	12	2.76
9	12	2.76
10	4	0.92
> 10	65	14.94
Total	435	100

(continued on next page)

depreciation). While we maintain our focus on tax avoidance, as opposed to more extreme tax aggressiveness, we make no formal hypotheses on the types or mechanisms of avoidance in which target firms engage. As such, we consider four broad constructs of tax avoidance that are well established in the literature and, in particular, are consistent with other studies examining tax avoidance in the agency cost context (Desai and Dharmapala 2006, 2009; Chen et al. 2010).

TABLE 1 (continued)

Panel C: Industry Distribution of Sample Firm-Years (per two-digit SIC industry classification)

SIC2	Industry Name	# of Obs.	Percent	SIC2	Industry Name	# of Obs.	Percent
1	Agricultural Production—Crops	8	0.27	45	Transportation by Air	13	0.44
7	Agricultural Services	3	0.10	47	Transportation Services	5	0.17
10	Metal, Mining	15	0.50	48	Communications	112	3.76
12	Coal Mining	13	0.44	49	Electric, Gas, and Sanitary Services	64	2.15
13	Oil and Gas Extraction	88	2.95	50	Wholesale Trade—Durable Goods	70	2.35
14	Nonmetallic Minerals, except Fuels	6	0.20	51	Wholesale Trade—Nondurable Goods	45	1.51
15	General Building Contractors	16	0.54	52	Building Materials and Gardening Supplies	2	0.07
16	Heavy Construction, Except Building	9	0.30	53	General Merchandise Stores	27	0.91
17	Special Trade Contractors	6	0.20	54	Food Stores	11	0.37
20	Food and Kindred Products	51	1.71	55	Automotive Dealers and Service Stations	10	0.34
21	Tobacco Products	4	0.13	56	Apparel and Accessory Stores	33	1.11
22	Textile Mill Products	14	0.47	57	Furniture and Home Furnishings Stores	10	0.34
23	Apparel and Other Textile Products	25	0.84	58	Eating and Drinking Places	42	1.41
24	Lumber and Wood Products	19	0.64	59	Miscellaneous Retail	87	2.92
25	Furniture and Fixtures	21	0.70	60	Depository Institutions	176	5.90
26	Paper and Allied Products	18	0.60	61	Non-depository Institutions	33	1.11

42	Trucking and Warehousing	13	0.44	87	Engineering and Management Services	62	2.08
44	Water Transportation	9	0.30	99	Non-classifiable Establishments	13	0.44

The sample consists of 2,981 hedge fund activist events initiated from 1994 to 2008. Panel A presents the frequency of activist events by years. Panel B shows the participation frequency of hedge fund activists. Panel C shows the industry distribution of sample firm-years (per two-digit SIC Industry Classification).

A firm's effective tax rate (ETR) is a popular metric for evaluating a firm's ability to minimize income taxes. We compute our first measure of tax avoidance as follows:[11]

$$Current\ ETR_{i,t} = (Total\ Tax\ Expense_{i,t} - Deferred\ Tax\ Expense_{i,t})/(Pretax\ Income_{i,t} - Special\ Items_{i,t}).$$

Current ETR captures tax strategies that give rise to both permanent and temporary book-tax differences through their exclusion of deferred tax expense. We regard *Current ETR* as a suitable measure of tax avoidance in the context of hedge fund activism, since funds could benefit from both tax reduction and tax deferral strategies. A lower *Current ETR* suggests that the firm is paying a smaller portion of its pretax book profits to taxing authorities, and is more effectively avoiding income taxes than firms with a higher *Current ETR*. Consistent with prior literature (e.g., Badertscher et al. 2010a; Chen et al. 2010), we restrict *Current ETR* to fall in the interval [0, 1].

Dyreng et al. (2008) propose an alternative version of the effective tax rate. They use the actual cash taxes paid (disclosed on the statement of cash flows) in the numerator, while retaining the traditional denominator. One advantage of this metric is that it takes into account tax benefits not recognized on the income statement, such as the tax benefits of employee stock options pre-SFAS 123R.[12] Furthermore, cash taxes paid are also free from possible accrual manipulation used to manage after-tax earnings. We use the cash effective tax rate (*Cash ETR*) as our second measure of tax avoidance, and similarly limit *Cash ETR* to fall within [0,1].[13] Specifically:

$$Cash\ ETR_{i,t} = Taxes\ Paid_{i,t}/(Pretax\ Income_{i,t} - Special\ Items_{i,t}).$$

The two remaining measures are based on book-tax differences. First, we calculate the Manzon and Plesko (2002) book-tax difference (*MP_BTD*) as follows:

$$MP\_BTD_{i,t} = \Big(Domestic\ Income_{i,t} - (Current\ Federal\ Income\ Tax\ Expense_{i,t}/0.35) - State\ Income\ Tax\ Expense_{i,t} - Other\ Income\ Tax\ Expense_{i,t} - Equity\ Income_{i,t}\Big)/(Total\ Assets_{i,t-1}).$$

We focus on domestic BTD first, because our sample of hedge fund activism targeted firms tend to be small and generally have insignificant amounts of foreign income, with average foreign income as a percentage of total income being only about 3.4 percent.[14] In addition, 70 percent of our observations have no foreign income in the event period of five years before and after the hedge fund activism. Second, focusing on domestic BTD avoids the problems associated with inferring applicable foreign tax rates (Manzon and Plesko 2002; Desai and Dharmapala 2009). Multiplying foreign tax expense by the U.S. federal statutory rate to estimate foreign tax liabilities in the calculation of total BTD is problematic, as studies document that U.S. firms (especially those with tax haven subsidiaries) tend to pay a much lower rate on foreign income (e.g., Dyreng and Lindsey 2009). Finally, this approach makes our analysis more directly comparable to prior literature (e.g., Desai and Dharmapala 2006, 2009; Chen et al. 2010). Large values of *MP_BTD* indicate greater levels of tax avoidance.

---

[11] We exclude special items from the denominator for two reasons: (1) special items can be quite large and lead to volatile annual ETR measures (Dyreng et al. 2008), and (2) special items include restructuring charges and other nonrecurring charges that might result from operational changes following hedge fund activism. Untabulated analyses show that our results are robust to the inclusion of special items in the denominator, as well as to the use of the overall ETR.

[12] Before SFAS 123R, firms could deduct stock option expenses for tax purposes and record this benefit as paid-in capital.

[13] Dyreng et al. (2008) show that the one-year cash ETR measure is an unreliable measure of long-run tax avoidance with evidence of low correlation between one-year rates with rates calculated over five- and ten-year periods, but do not suggest the short-run measure is without merit. For our event study research setting, one-year measures appear to be more appropriate for the examination of year-to-year changes in tax avoidance. In addition, in the context of an event study, finding changes in a long-run cash effective tax rate would be difficult, because years prior to the event will still be more heavily weighted in the avoidance measures for the post-intervention years. Finally, the robust results across the three additional metrics should partially mitigate the concern over the validity of one-year measure of cash ETR. Alternatively, we estimate three-year cash ETRs before and after the hedge fund intervention, respectively, and find our inferences are unaltered.

[14] There are two reasons why hedge funds tend to target smaller firms with minimum foreign activities. First, these firms have fewer resources for value-enhancing activities such as tax avoidance and, thus, could benefit more from hedge fund interventions. Second, fund activists are better able to influence and implement business strategies in firms that are small and less complex than multinational firms.

MP_BTD captures tax strategies that lead to both permanent and temporary differences between book income and taxable income. Desai and Dharmapala (2006) note that federal tax expense, used to calculate taxable domestic income, is affected by income-changing discretionary accruals used for earnings management purposes. To mitigate the influence of earnings management strategies on book-tax differences, they compute an alternative book-tax difference metric by regressing *MP_BTD* on total accruals (*TA*) measured using the cash flow method suggested by Hribar and Collins (2002):[15]

$$MP\_BTD_{i,t} = \beta_1 TA_{i,t} + \mu_i + \varepsilon_{i,t}.$$

The residual of this regression (ε), which is expected to be largely free of earnings management (or at least accruals management), is the Desai and Dharmapala (2006) book-tax difference (*DD_BTD*). Similar to *MP_BTD*, larger values of *DD_BTD* imply greater levels of tax avoidance.[16]

There are limitations associated with empirical tax avoidance measures, including those used in our study. First, as noted by Bernard (1984) and Hanlon and Heitzman (2010), these measures do not capture conforming tax avoidance or those strategies reducing both book and taxable income, such as debt interest. Second, measures of book-tax differences are essentially an "ETR differential," reflecting the difference between the statutory tax rate and the GAAP ETR, since taxable income is estimated by "grossing up" reported tax expense by the statutory tax rate (Hanlon and Heitzman 2010, 142). These four measures are not independent and, therefore, neither are the corresponding tests based on these measures.

IV. PRIMARY RESULTS

Propensity Score Matching

Brav et al. (2008) show that hedge fund activists select their target firms based on certain firm characteristics. Our results will be biased if these *ex ante* characteristics of target firms lead to future increases in our tax avoidance measures even without the hedge fund intervention. Another concern is that a contemporaneous upward trend in tax avoidance occurring to all firms drives our results. To control for a potential selection bias and market-wide changes of tax avoidance, we use the propensity score matching method to construct a sample of control firms.[17] The propensity score is the predicted probability of becoming a hedge fund target in the next year, estimated from a logistic regression model, as in Brav et al. (2008, Table IV). Specifically, we regress a dummy variable of being targeted by hedge funds on the lagged values of firm size, Tobin's Q, sales growth, return on assets, debt-to-equity ratio, annual dividend yield, R&D expense, Herfindahl index, number of analysts following the firm, percentage of institutional ownership, and year dummies.[18] We estimate this logistic regression for all firms in the Compustat database with available data from 1994 to 2008, and then use the obtained coefficients to estimate the propensity score for each firm.[19] We identify non-target firms with the closest propensity score of the target firms, compute the differences between levels of target firms and those of matched control firms for all variables, and use the resulting adjusted values (i.e., the differences) for our empirical analysis.

---

[15] μ_i is used to indicate the firm fixed-effect.

[16] Hanlon and Heitzman (2010) provide a comprehensive discussion of these and other tax avoidance measures.

[17] Propensity score matching is a widely used method to deal with selection bias, and measures the "treatment effect" as the outcome for the treated firm minus the outcome for an untreated firm with equal treatment probability (e.g., Li and Prabhala 2007; Lawrence et al. 2011). One advantage of using propensity score matching is to control for a general time-specific temporal trend. Since our sample does not have calendar time clustering, using simple industry matching (e.g., adjusting the variables for industry means) can control for such a trend. However, matching on industry may not sufficiently control for the self-selection bias. We find similar, but slightly weaker, results when using only industry control samples.

Univariate Test

Table 2 provides univariate tests of tax avoidance for target firms surrounding hedge fund activist events. For each measure, we present the mean adjusted annual levels from the year prior to the activist event to the second year after the event (Event Year 0 being the year of the intervention announcement), as well as the changes in these adjusted annual variables. Specifically, we adjust the values of tax avoidance measures by subtracting the corresponding value for the matched firm from that for the sample firm. For each tax avoidance measure, we require a constant sample with non-missing data across the event year window [−1, +2] and, thus, the sample size varies across different tax avoidance measures.

An important premise of our hypothesis is that the tax avoidance level of the target firm must be sufficiently low to motivate hedge funds' attempts to improve tax planning.[20] The "Adjusted Annual Values" section of Table 2 shows that in Year −1, the *Current ETR* (*Cash ETR*) has an average of 0.108 (0.143), suggesting that target firms have significantly higher effective tax rates than matched control firms prior to the intervention.[21] The two book-tax difference measures are significantly negative (−0.036 for *MP_BTD*, and −0.021 for *DD_BTD*), indicating lower book-tax differences relative to control firms. Such tax inefficiency (as indicated by significantly positive ETRs and negative BTDs) may have attracted hedge fund activists' interest to promote a change. To test whether hedge funds target firms with low tax avoidance levels, we estimate the association between tax avoidance in Year *t* and the probability of being targeted by hedge fund activists in Year *t*+1 by adding our tax measures to the logistic regression model used by Brav et al. (2008), as described previously. We find (untabulated) that our two ETR measures are significantly and positively associated with the likelihood of being targeted.[22] Taken together, our results are consistent with inefficient tax planning being a potential motivating factor for hedge funds to intervene.

---

[18] In an alternative specification, we also include the prior tax avoidance level in the estimation of propensity scores to address the concern that target firms and control firms could be significantly different in tax avoidance levels before the intervention. We then repeat the analyses in Table 2 and Table 5, and find results that are largely consistent with those reported in the paper.

[19] We find largely similar results as in Brav et al. (2008). For conciseness, the results from the targeting likelihood regressions are not tabulated, but are available upon request.

[20] We thank the original editor, Thomas Omer, for raising this point.

[21] As previously discussed, we adjust values of all variables by those of matched control firms and use the resulting adjusted values for our empirical analysis. Thus, all values of variables reported in this paper are adjusted values, and statistical significance levels of these values indicate whether there are significant differences between target firms and matched control firms.

[22] The coefficients on the two BTD measures are negative and statistically insignificant.

TABLE 2

Changes in Tax Avoidance after Hedge Fund Intervention

	Current ETR	*Cash ETR*	*MP_BTD*	*DD_BTD*

No. of Observations	554	650	815	767

*, **, *** Indicate statistical significance at the 10 percent, 5 percent, and 1 percent levels (one-sided), respectively.
This table reports the mean adjusted annual levels of tax avoidance for target firms around hedge fund activist events from Event Year −1 to Event Year +2, with Event Year 0 being the year of the intervention announcement, as well as the changes in these adjusted annual variables. Adjusted values are computed as the differences between the levels of event firms and the levels of the matched control firms. Control firms are identified as firms that have never been targeted by hedge funds during our sample period, but have the closest propensity scores to target firms. Propensity score is the predicted probability of becoming a hedge fund activism target in the next year, estimated from the model as in Brav et al. (2008, Table IV). For each tax avoidance measure, we require a constant sample with non-missing data across the event window [−1, +2]. In the top section, we test whether the tax avoidance levels of target firms are statistically different from those of control firms in each event year. In the bottom section, we test whether the changes in tax avoidance levels of target firms differ significantly from those of control firms. Appendix B contains the variable definitions.

Next, we turn to changes in adjusted tax avoidance rates after hedge fund activism events. The "Changes in Adjusted Annual Values" section of Table 2 shows that target firms exhibit greater improvement in tax avoidance than matched control firms after the activist event. Specifically, for both *Current ETR* and *Cash ETR*, the differences between the year prior to the intervention and the year after (−0.039 and −0.038, respectively) are negative and significant. We find that differences between the year prior to the intervention and Year *t*+2 are even larger for both *Current ETR* and *Cash ETR* (−0.065 and −0.054, respectively), suggesting further increases in tax avoidance during Year *t*+2. The univariate results for the book-tax difference measures generate similar inferences. The measures show similar increases in book-tax differences in both years following the intervention for both *MP_BTD* (0.079 and 0.078, respectively) and *DD_BTD* (0.025 and 0.019, respectively). In summary, univariate tests across all four tax avoidance measures support our hypothesis, indicating increases in tax avoidance following hedge fund intervention.

Direct Effects versus Indirect Effects

Since hedge fund interventions often elicit profound and multi-dimensional changes in target firms (Brav et al. 2010), our results in Table 2 could be driven by either the direct effects of activism on tax avoidance as a result of improvements in tax planning, or by indirect effects arising from changes in the firm's operating performance, capital structure, and investments. For example, Brav et al. (2008) show that target firms experience significant increases in leverage, and the tax avoidance literature (e.g., Badertscher et al. 2010a, 2010b) finds that the level of leverage affects a firm's incentives for tax planning. Firms with more debt enjoy a larger interest tax shield that reduces income tax liabilities and may lower the need for tax planning or other tax shields (Badertscher et al. 2010a, 2010b). Acknowledging this possibility, we conduct additional tests to explore to what extent the indirect effects of activism influence our findings of increases in tax avoidance. First, we examine whether changes in performance, leverage, and investments cause the changes in tax avoidance after the fund intervention. Second, we use a multivariate levels regression model to control for known tax determinants, so that our variables of interest can better capture the direct effects of activism on tax. Finally, we investigate the impact of hedge fund activist characteristics, especially those indicating their interest or knowledge in tax efficiency.

Changes in Performance, Leverage, and Investments after Hedge Fund Intervention

We first examine changes in the target firms' operating performance (measured by ROE), capital structure (measured by leverage), and investments (measured by PPE and intangible assets) to assess the possibility that changes in these variables lead to the increases in tax avoidance. Table 3 reports the mean adjusted annual levels of ROE, leverage, PPE, and intangible assets from Event Year −1 to Event Year +2 for target firms, as well as the changes in these adjusted annual variables. Specifically, we adjust all variables by subtracting the corresponding value for the matched firm from that for the sample firm.

In the "Changes in Adjusted Annual Values" section of Table 3, we find no significant changes in pretax ROE, implying that our results on tax avoidance should not be driven by changes in operating performance.[23] However, we do find significant increases in leverage, similar to the findings in Brav et al. (2010). Leverage has no direct effect on our tax measures since interest expense is deductible for both book income and taxable income, and our measures capture only nonconforming tax avoidance (Bernard 1984; Hanlon and Heitzman 2010). However, leverage may be correlated with firm tax strategy due to the impact of a debt tax shield on a firm's incentives for tax planning (e.g., Badertscher et al. 2010a, 2010b). We find that target firms experience decreases in property, plant, and equipment (PPE), which is consistent with the findings in Brav et al. (2010), suggesting that activism cuts slack for target firms by tightening monitoring in investment decisions. PPE is subject to nonconforming book and tax accounting rules and can be used to increase tax avoidance (e.g., using accelerated depreciation of PPE under tax accounting rules). Decreases in PPE allow for less reduction in tax liabilities, due to accelerated tax depreciation, and also lead to lower levels of tax avoidance. Hence, decreases in PPE following the intervention cannot explain our documented increases in tax avoidance. Finally, we find no significant increases in intangible assets.

To rule out changes in firm fundamentals as alternative explanations for our results, we construct several control samples based on changes in four variables (ROE, leverage, PPE, and intangible assets) and compare changes in tax avoidance between our target sample and control samples. Specifically, we identify four separate control samples matched on changes in ROE, leverage, PPE, and intangible assets, respectively.[24] We then compare changes in tax avoidance around hedge fund intervention between the target sample and each of the control samples. Consistent with our prediction, the untabulated results indicate that target firms experience significantly greater increases in tax avoidance than their control firms in each of these matching samples.

---

[23] In a univariate test, Brav et al. (2008) find that target firms' performance deteriorates during the event year and eventually recovers and exceeds pre-intervention performance in *Year +2*. We find a similar trend that ROE improves in *Year +2*, but this change is not statistically significant. The difference between our findings and theirs is likely due to sample differences. For robustness, we analyze their sample (which is a subset of our sample) and find similar results.

[24] We match target firms and control firms on only one dimension at a time (e.g., change in PPE) because very few control firms experience changes in more than one dimension similarly to the target firms.

TABLE 3

Changes in Performance, Leverage, and Investments after Hedge Fund Intervention

*, **, *** Indicate statistical significance at the 10 percent, 5 percent, and 1 percent levels (one-sided), respectively.
This table reports the mean adjusted annual levels of performance, leverage, and investments for target firms around hedge fund activist events from Event Year −1 to Event Year +2, with Event Year 0 being the year of the intervention announcement, as well as the changes in these adjusted annual values. Adjusted values are computed as the differences between the levels of event firms and the levels of the matched control firms. Control firms are identified as firms that have never been targeted by hedge funds during our sample period, but have the closest propensity scores to target firms. Propensity score is the predicted probability of becoming a hedge fund activism target in the next year, estimated from the model as in Brav et al. (2008, Table IV). For each firm characteristic measure, we require a constant sample with non-missing data across the event window [−1, +2]. In the top section, we test whether the performance, leverage, and investment levels of target firms are statistically different from those of control firms in each event year. In the bottom section, we test whether the changes in performance, leverage, and investment levels of target firms differ significantly from those of control firms. Appendix B contains the variable definitions.

Alternatively, we can control for indirect effects using a multivariate framework by explicitly including these variables in the regression model. We report our multivariate results in the next two subsections.

Multivariate Test

In testing family owners' influence on tax avoidance, Chen et al. (2010) suggest the inclusion of a comprehensive set of variables in a levels regression model to control for indirect effects. Chen et al. (2010, 44, 49–50) explain that these control variables are intended to capture the indirect effects on tax avoidance measures arising from firm characteristics, and those caused by specific tax treatments that differ from Generally Accepted Accounting Principles (GAAP).[25] We follow their approach by including a comprehensive set of variables, so that the variables of interest (i.e., event year dummies) in the multivariate regressions are likely to capture the direct effects of hedge fund activism on tax avoidance.

One concern is that our regression equation includes several tax determinant variables that can be a part of the tax avoidance strategies promoted by hedge fund activists, and controlling for these variables could purge out some "direct effects" of hedge fund activism on corporate tax avoidance, biasing against finding significant coefficients on our key variables of interest. However, as Chen et al. (2010, 49–50) note, controlling for tax tool variables is not "throwing the baby out with the bath water," in the sense that these variables simply control for the average tax avoidance associated with those variables. Our model only removes the average effects of these tax tools so that the year dummy variables still potentially capture the changes in firms' tax avoidance resulting from the direct effects.

---

[25] Other studies use the same approach of controlling for firm characteristics in multivariate regressions to ensure that other firm characteristics do not cause the differences in the outcome variable being investigated, including Ashbaugh-Skaife et al. (2009) and Graham et al. (2008).

We estimate Equation (1) for each of the tax avoidance measures. The sample includes firm-years of target firms from Event Year −1 to Event Year +2 with required data:

$$\begin{aligned} Tax\ Measure_{i,t} = {} & \beta_0 + \beta_1 DYear0_{i,t} + \beta_2 DYear1_{i,t} + \beta_3 DYear2_{i,t} + \beta_4 ROE_{i,t} + \beta_5 Leverage_{i,t} \\ & + \beta_6 DNOL_{i,t} + \beta_7 \Delta NOL_{i,t} + \beta_8 Foreign\ Income_{i,t} + \beta_9 PPE_{i,t} \\ & + \beta_{10} Intangible\ Asset_{i,t} + \beta_{11} Equity\ Income_{i,t} + \beta_{12} MTB_{i,t-1} + \beta_{13} Size_{i,t-1} \\ & + Year\ Dummies + Industry\ Dummies + \varepsilon_{i,t}. \qquad (1) \end{aligned}$$

Tax Measure is the firm's *Current ETR*, *Cash ETR*, *MP_BTD*, or *DD_BTD* in period *t*. *DYear0*, *DYear1*, and *DYear2* are dummy variables that equal 1 if the current year is the Event Year 0, +1, and +2, respectively, and 0 otherwise. For the ETR (BTD) measures, a negative (positive) coefficient on *DYear1* and *DYear2* variables indicates higher levels of tax avoidance in Event Year +1 and Event Year +2 relative to Event Year −1. All variables in the regressions incorporate adjustments for the corresponding values of the propensity score matched control firms.

We include a number of control variables that have been shown by prior literature to be potential determinants of tax avoidance (e.g., Manzon and Plesko 2002; Mills 1998; Rego 2003; Dyreng et al. 2008; Frank et al. 2009; Chen et al. 2010; McGuire et al. 2011, 2012). Return on equity (*ROE*) is calculated as operating income (computed as pretax income minus extraordinary items) scaled by the lagged book value of equity, and measures a firm's financial performance. Gupta and Newberry (1997) report a positive relation between ETRs and firm profitability. They suggest that higher income is associated with higher marginal tax rates and, hence, firms with higher profits will tend to exhibit higher ETRs. However, Rego (2003), Frank et al. (2009), Rego and Wilson (2010), and McGuire et al. (2012) document a positive relation between firm profitability and tax avoidance. They argue that more-profitable firms have stronger incentives due to the larger potential savings, and more resources to engage in tax avoidance. In addition, Manzon and Plesko (2002) and Rego (2003) propose that more-profitable firms have lower costs of tax avoidance, since they can make more efficient use of tax deductions, credits, and exemptions relative to less-profitable firms, resulting in lower effective tax rates and greater book-tax differences.

Since interest expense is deductible for taxable income while dividend payments are not, a firm's capital structure is an important determinant of its expected tax liability. We include a firm's *Leverage* (long-term debt scaled by lagged total assets) to control for the effect of debt on firms' incentives in tax planning. As discussed earlier, since interest expenses are deductible for both book and tax incomes, nonconforming tax avoidance measures, such as effective tax rates and book-tax differences, will not capture tax avoidance resulting from changes in leverage (Bernard 1984; Hanlon and Heitzman 2010, 142). However, the tax deductibility of the interest will have an impact on the firm's tax-planning incentives. For instance, highly leveraged firms may have either a stronger motivation to avoid taxes in order to preserve cash to service the heavy debt burdens, or a weaker motivation due to the debt tax shield (Badertscher et al. 2010b).

Utilization of prior operating loss carryforwards (NOL) should reduce current period tax burdens. To control for this effect, we follow Chen et al. (2010) and include ΔNOL, the change in a firm's tax loss carryforwards from prior to current period, scaled by lagged total assets. The association between ΔNOL and our tax avoidance measures depends on whether it results in nonconformity between taxable income and book income. *Ceteris paribus*, a decrease in NOL implies that firms are using NOLs to lower their taxable income. When taxable income is lower, book-tax differences (BTD) will be larger and effective tax rates (ETR) will be lower. On the other hand, an increase in NOL due to current period's loss should not affect current taxable income, since its tax reduction benefits will be realized in future profitable years.[26] Taken together, the average relation between ΔNOL and tax avoidance can be significantly negative. Prior studies generally predict and find a negative relation between ΔNOL and BTD and a positive relation between ΔNOL and ETR. For example, Cooper and Knittel (2010) argue that those firms utilizing an NOL should have lower effective tax rates than their counterparts not using an NOL. Mackie (1999) suggests that the rising profitability during the 1990s allowed firms to effectively utilize NOLs and enjoy lower average tax rates during that time period. Manzon and Plesko (2002), Chen et al. (2010), and McGuire et al. (2011) all find that ΔNOL is positively (negatively) associated with ETR (BTD). To control for the existence of such exercisable benefits, we follow Chen et al. (2010) by including *DNOL*, an indicator variable equal to 1 if the firm had a positive tax loss carryforward at the beginning of the year, and 0 otherwise.

The variables *Foreign Income*, *PPE*, *Intangible Assets*, and *Equity Income* capture firm characteristics that by statute affect a firm's income tax liability. We include *Foreign Income*, the firm's foreign income scaled by lagged total assets, to control for book income that may not result in a current tax liability. This is because foreign profits are, in general, not subject to U.S. tax until repatriated (e.g., Rego 2003).[27] A firm's book income generally differs from its tax income because of different treatments of certain transactions. For instance, levels of depreciation expense calculated under book and tax rules are rarely equivalent and, therefore, firms with higher levels of depreciable assets may exhibit greater book-tax differences simply attributable to heterogeneous statutory requirements. Accordingly, we include the firm's property, plant, and equipment scaled by lagged assets, *PPE*, as an explanatory variable. Similarly, amortization rules for intangible assets vary between book and tax accounting rules. In particular, purchased goodwill is tested for impairment under GAAP, but amortized over 15 years under U.S. tax rules. Similar to prior literature (e.g., Chen et al. 2010), we note the importance of including *Intangible Asset* (intangible assets scaled by lagged total assets) because of the statutory differences in cost recovery and asset valuation. Income from affiliated entities is included in book income when recognized under the equity method, but is not necessarily included in taxable income. Thus, we control for this book-tax difference by including in our regression the amount of *Equity Income* (equity income in earnings scaled by lagged assets).

We also control for *Size* (natural logarithm of the firm's market value of equity) and *MTB* (market value of equity scaled by book value of equity). Political cost theory proposes that larger firms pay higher political costs, including taxes (Watts and Zimmerman 1986). Alternatively, larger firms have greater resources to influence the political process in their favor and to engage in tax planning (Siegfried 1972). Growth firms may be more likely to purchase tax-favored assets (e.g., Chen et al. 2010) and have more unrecovered capital for tax purposes, creating tax benefits through depreciation and amortization. On the other hand, mature firms may have more experience in tax planning. Finally, we include industry and year fixed-effects to capture variations attributable to these sources.

After removing observations with missing values for the control variables or tax avoidance metrics, our regression analyses are performed on the remaining firm-years for each of the four tax avoidance measures, with corresponding descriptive statistics reported in Panel A of Table 4. The mean (median) values for *Current ETR*, *Cash ETR*, *MP_BTD*, and *DD_BTD* are 0.102 (0.014), 0.138 (0.061), –0.023 (0.000), and –0.009 (0.008), respectively. The Pearson correlations in Panel

---

[26] In addition, such deferred tax benefits are not included in our ETR tax measures, because current tax expense and cash tax taxes paid do not contain deferred tax benefits.

[27] Firms should recognize deferred tax expense on foreign earnings which are not considered permanently reinvested, but minimal guidance in GAAP regarding the definition of "permanently reinvested" results in wide variation in the application of this rule in practice.

B of Table 4 show that, as expected, the two ETR measures are significantly and negatively correlated with the two BTD measures. Across all four tax avoidance measures, tax avoidance levels are positively correlated with *ROE*, *Foreign Income*, *Equity Income*, and *Lagged Size*, and negatively correlated with ΔNOL.

Table 5 presents the results of the four regressions. The coefficients on the dummy variables for the year of the intervention (*DYear0*) are negative and significant for *Cash ETR* (–0.034), and positive and significant for *MP_BTD* (0.050). Further, the coefficients for the first year following the event (*DYear1*) are negative and significant for *Current ETR* (–0.039) and *Cash ETR* (–0.067), and positive and significant for *MP_BTD* (0.081) and *DD_BTD* (0.028), suggesting an increase in tax avoidance in the post-intervention period.[28] These increases in tax avoidance persist into the second event year, with unchanged signs and significant coefficients for *DYear2* for three measures (–0.079 for *Current ETR*, –0.111 for *Cash ETR*, 0.102 for *MP_BTD*). The coefficient for *DD_BTD* (0.024) has an unchanged sign, but is insignificant. We also find the changes in tax avoidance provide substantial economic benefits to target firms. The regression coefficients on our event year dummies reflect the average changes in our tax avoidance measures. For example, we find that target firms experience decreases in effective tax rates that range from 3.9 percent to 11.1 percent, which equates to dollar tax savings between $319,800 and $910,200 for an average firm, given that the mean pretax income of our sample is $8.2 million.

With regard to the coefficients on control variables, *ROE* is negatively associated with both *Current ETR* and *Cash ETR*, similar to the findings in Rego (2003), Rego and Wilson (2010), and McGuire et al. (2012). This finding is consistent with the argument that more-profitable firms have stronger incentives and more opportunities to engage in tax avoidance (Rego 2003; Manzon and Plesko 2002). Change in tax loss carryforwards (ΔNOL) is positively (negatively) associated with ETR (BTD), similar to the findings in Manzon and Plesko (2002), Chen et al. (2010), and McGuire et al. (2011). Our findings are consistent with the argument that the utilization of NOL carryforwards reduces current period tax liabilities. As expected, and consistent with prior studies (Rego 2003; Gupta and Newberry 1997; Chen et al. 2010; Rego and Wilson 2010; McGuire et al. 2012), *Foreign Income*, *PPE*, *Intangible Asset*, and *Equity Income* are negatively associated with the two ETR measures. Finally, we find larger firms exhibit greater tax avoidance, supporting Siegfried's (1972) assertion that larger firms have greater resources to engage in tax planning. To further examine the association between control variables and tax avoidance measures, we also conduct multivariate tests for each tax avoidance measure with only control variables. The results are similar to those with the inclusion of the event year indicators. In summary, the results from the multivariate tests in Table 5 show that increases in tax avoidance following hedge fund interventions are not driven by the indirect effects arising from changes in firm characteristics following the interventions.

Impact of Hedge Fund Activists' Characteristics

To further strengthen the validity of our results, we extend our analysis by investigating whether changes in tax avoidance of target firms following fund intervention are related to activists' heterogeneity in incentives and abilities. To identify hedge funds' incentive, we search for indications of their interest and knowledge in tax planning from their filings. We download all the

---

[28] The changes in the first year (Year +1) appear dramatic. Note, also, that the changes do not reverse in Year +2, implying that hedge funds identify target firms whose tax under-avoidance can be improved in the short term (within two years). Similarly, Brav et al. (2008) also report dramatic changes in target firms' policies (e.g., compensation and dividend payout) in Year +1, indicating that activists could initiate and implement policy changes rather quickly. The large changes could potentially be due to measurement issues. However, we use four measures and find robust significant changes for each in Year +1. Hence, we believe the changes in Year +1 are not solely due to our empirical measures.

This table presents descriptive statistics and Pearson correlations for the sample that includes firm-years of target firms in the event window [−1, +2] with required data, where Event Year 0 is the year of the intervention announcement. Panel A reports descriptive statistics of variables used in the multivariate regressions. We compute and report adjusted values that are computed as the differences between the levels of the event firms and the levels of the matched control firms. Control firms are identified as firms that have never been targeted by hedge funds during our sample period, but have the closest propensity scores to target firms. Propensity score is the predicted probability of becoming a hedge fund activism target in the next year, estimated from the model as in Brav et al. (2008, Table IV). In Panel B, p-values are reported in parentheses. Appendix B has the variable definitions.

*, **, *** Indicate statistical significance at the 10 percent, 5 percent, and 1 percent levels, respectively.

This table presents the results on changes in tax avoidance of target firms around hedge fund activist events. The sample includes firm-years of target firms in the event window [−1, +2] with required data, where Event Year 0 is the year of the intervention announcement. For all dependent and control variables in the regressions, we adjust their values by the levels of the matched control firms. Control firms are identified as firms that have never been targeted by hedge funds during our sample period, but have the closest propensity scores to target firms. Propensity score is the predicted probability of becoming a hedge fund activism target in the next year, estimated from the model as in Brav et al. (2008, Table IV). Intercept, industry, and year dummies are included, but not reported. t-statistics reported in parentheses are based on heteroscedasticity robust standard errors clustered by firm. Appendix B contains the variable definitions.

SC 13D and 13D/A filings for our 2,981 hedge fund activist events (17,152 filings). Using a full-text search program, we identify 98 events (involving 59 hedge funds) in which hedge fund activists exhibit their interest or knowledge in target firms' tax issues. Due to the opaque nature of tax planning and the potential risk associated with its tax strategy being ruled as improper (Desai and Dharmapala 2006, 2009; Chen et al. 2010), it is likely that many hedge fund activists refrain from explicitly expressing their interest in tax issues or disclosing detailed tax-planning strategies in public filings.[29] To overcome the small-sample problem, instead of only focusing on these 98 special cases, we assume that the hedge fund activists associated with these events have interest and knowledge in tax issues and are more likely to exert influence over tax planning of their target firms.[30]

We also employ two other proxies for hedge funds' ability to implement tax changes. Specifically, we conjecture that hedge funds with more activism experience and greater past success of inducing tax changes have more ability to promote changes in their target firms. The regression model for these tests is specified below:

$$\begin{aligned} Tax\,Measure_{i,t} = {} & \beta_0 + \beta_1 DYear0_{i,t} + \beta_2 DYear1_{i,t} + \beta_3 DYear2_{i,t} + \beta_4 ActivistChar_{i,t} \\ & + \beta_5 DYear0_{i,t} \times ActivistChar_{i,t} + \beta_6 DYear1_{i,t} \times ActivistChar_{i,t} \\ & + \beta_7 DYear2_{i,t} \times ActivistChar_{i,t} + \beta_8 ROE_{i,t} + \beta_9 Leverage_{i,t} + \beta_{10} DNOL_{i,t} \\ & + \beta_{11} \Delta NOL_{i,t} + \beta_{12} Foreign\,Income_{i,t} + \beta_{13} PPE_{i,t} + \beta_{14} IntangibleAssets_{i,t} \\ & + \beta_{15} EquityIncome_{i,t} + \beta_{16} MTB_{i,t-1} + \beta_{17} Size_{i,t-1} + Year\,Dummies \\ & + Industry\,Dummies + \varepsilon_{i,t}, \end{aligned} \tag{2}$$

where *ActivistChar* represents *Activists' Experience*, *Tax Avoidance Changes in Past Activist Events*, and *Activist Exhibiting Tax Interest or Knowledge*, respectively, in separate tests. Specifically, *Activists' Experience* is proxied by the number of prior intervention events the fund activist has initiated in the past five years, *Tax Avoidance Changes in Past Activist Events* is proxied by the average changes in tax avoidance in the firms targeted by the activist during the past five years, and *Activist Exhibiting Tax Interest or Knowledge* is an indicator variable if the hedge fund activist is one of these 59 activists that have exhibited tax interest or knowledge in one of their 13D or 13D/A filings during the sample period. To test whether the increase in tax avoidance following interventions is affected by these activist characteristics, we interact *DYear0*, *DYear1*, and *DYear2*, respectively, with *ActivistChar*. We also adjust all dependent and control variables for the levels of the propensity score matched control firms.

Table 6 reports the results of estimating Equation (2). In Panel A, we find no significant coefficients on these interactions between *DYear0*, *DYear1*, and *DYear2* and *Activists' Experience*. However, we find that the coefficients on the interactions between *DYear1*, *DYear2*, and *Tax Avoidance Changes in Past Activist Events* are significantly positive when the dependent variables are *Current ETR*, *Cash ETR*, and *DD_BTD*. The results indicate that activists' past success in implementing tax changes is positively and significantly associated with increases in the target firm's tax avoidance in the current intervention. Table 6, Panel B, shows that the interactions between *DYear1*, *DYear2*, and dummy variable *Activist Exhibiting Tax Interest or Knowledge* are

---

[29] We classify these interventions into the following five categories: (1) the activist states that she will discuss tax issues with managers, (2) the activist emphasizes the importance of tax efficiency in a specific business context (such as spin-off of a subsidiary in a tax efficient manner), (3) the activist applies advanced tax knowledge in her proposal to the target firm's manager to improve firm performance, (4) the activist explicitly suggests tax strategies, and (5) the activist indicates that she has either a tax director or has an external tax consultant. There are only around 20 cases in the fourth category.

[30] We also compare these 98 cases with other cases targeted by the same hedge fund activists, and find that the increases in tax avoidance levels associated with these 98 cases are greater than for other activist events (untabulated).

TABLE 6 (continued)

---

*, **, *** Indicate statistical significance at the 10 percent, 5 percent, and 1 percent levels, respectively.

This table presents the results on the impact of hedge fund activists' characteristics on changes in tax avoidance of target firms around the hedge fund activist events. The sample includes firm-years of target firms in the event window [−1, +2] with required data, where Event Year 0 is the year of the intervention announcement. *Activists' Experience* is measured by the number of intervention events initiated by the hedge fund activist during the past five years. (*Activists' Experience* is divided by 100 for exposition.) *Tax Avoidance Changes in Past Activist Events* is measured by the average changes in tax avoidance in the firms targeted by the hedge fund activist during the past five years. *Activist Exhibiting Tax Interest or Knowledge* is an indicator variable if the hedge fund activist has exhibited interest or knowledge in tax issues in one of her 13D or 13D/A filings during the sample period. For all dependent and control variables in the regressions, we adjust their values by the levels of the matched control firms. Control firms are identified as firms that have never been targeted by hedge funds during our sample period, but have the closest propensity scores to target firms. Propensity score is the predicted probability of becoming a hedge fund activism target in the next year, estimated from the model as in Brav et al. (2008, Table IV). Intercept, industry, and year dummies are included, but not reported. t-statistics reported in parentheses are based on heteroscedasticity robust standard errors clustered by firm. Appendix B contains the variable definitions.

No. of Observations	221	269	343	319

*, **, *** Indicate statistical significance at the 10 percent, 5 percent, and 1 percent levels (one-sided), respectively.
This table reports the mean adjusted annual levels of tax avoidance for target firms around hedge fund activist events from Event Year −1 to Event Year +5, with Event Year 0 being the year of the intervention announcement, as well as the changes in these adjusted annual values. Adjusted values are computed as the differences between the levels of event firms and the levels of the matched control firms. Control firms are identified as firms that have never been targeted by hedge funds during our sample period, but have the closest propensity scores to target firms. Propensity score is the predicted probability of becoming a hedge fund activism target in the next year, estimated from the model as in Brav et al. (2008, Table IV). For each tax avoidance measure, we require a constant sample with non-missing data across the event window [−1, +5]. In the top section, we test whether the tax avoidance levels of target firms are statistically different from those of control firms in each event year. In the bottom section, we test whether the changes in tax avoidance levels of target firms differ significantly from those of control firms. Appendix B contains the variable definitions.

negatively and significantly associated with *Current ETR* and *Cash ETR*. We also find that the interaction between *DYear1* and dummy variable *Activist Exhibiting Tax Interest or Knowledge* is positively and significantly associated with *DD_BTD*. The results indicate that target firms experience greater improvements in their tax planning if their activists are known for expressing their tax interest or knowledge in SC 13D filings.

In summary, our evidence shows that hedge fund activists differ systematically in their impact on target firms' tax avoidance.[31] Target firms of activists with greater past success or expertise in implementing tax changes experience greater increases in tax avoidance following intervention.

V. ADDITIONAL TESTS

Changes in Tax Avoidance in Five Years after the Intervention

We extend the univariate analyses in Table 2 to examine the longer-term persistence of changes in tax avoidance. Similar to Table 2, we require a constant sample across the period in an attempt to mitigate the survivorship bias. We also adjust all values of tax avoidance measures for the levels of the propensity score matched control firms. Table 7 shows that the decreases in effective tax rates do not reverse across the ETR measures of tax avoidance. For instance, the change from Event Year −1 to Event Year +5 is −0.081 for the *Current ETR*, −0.066 for the *Cash ETR*, 0.086 for the *MP_BTD*, and 0.043 for the *DD_BTD*, respectively; all significant at the 5 percent level. Results in Table 7 show that, in general, changes in tax avoidance after hedge fund intervention do not reverse, at least in the intermediate term, indicating that hedge funds' influence on target firms' tax planning is not limited to short-term only.

---

[31] We also conduct changes analysis, where we regress changes in tax avoidance on hedge fund characteristics and changes in control variables in Equation (2). Changes in both tax avoidance measures and control variables are computed relative to the levels in Year −1, and also adjusted for the corresponding values of control firms identified by propensity score matching. We find that all three hedge fund characteristics are associated with changes in tax avoidance. In particular, *Activists' Experience* is positively and significantly associated with changes in tax avoidance. Taken together, we conclude that both the levels and changes analyses provide evidence linking changes in corporate tax avoidance around intervention to hedge fund characteristics.

Is Increased Tax Avoidance Associated with Increased Use of Tax Sheltering?

We further analyze whether the increased tax avoidance is associated with target firms' increased use of high-risk, and potentially illegal, tax-planning strategies such as tax sheltering. The costs and benefits to engaging in a tax shelter are a frequent subject of interest in the literature. Graham and Tucker (2006) find that tax shelters provide firms with tax savings. Hanlon and Slemrod (2009) find a negative stock price reaction immediately following public revelation of a firm's involvement in a tax shelter. Firms have to balance the income-increasing and cash-saving benefits of aggressive tax planning with the potential monetary, reputation, and agency costs associated with such activities (Desai and Dharmapala 2006; Wilson 2009; Chen et al. 2010). Under certain circumstances, the benefits could be large enough to justify participation in a shelter. Thus, it is an empirical question as to whether hedge fund activist interventions are associated with an increase in the use of tax shelters. Wilson (2009) develops a model of firm characteristics to estimate the probability that a firm is currently engaging in tax sheltering based on firms publicly revealed to have been engaged in shelters. Lisowsky (2010) develops an alternative model using confidential IRS data for firms employing listed tax shelters.[32] Using the sheltering probability estimates from Wilson (2009) and Lisowsky (2010), we examine whether hedge fund activism is associated with increased probabilities of tax sheltering behaviors.[33] Untabulated results show no evidence that target firms are more likely to engage in tax sheltering after hedge fund intervention.[34] Our results, therefore, suggest that the greater tax savings achieved by target firms likely result from more efficient tax planning, rather than the use of egregious and risky tax evasion strategies.[35]

Do Hedge Fund Activists Simply Pick Target Firms that are Already Experiencing Increases in Tax Avoidance?

Brav et al. (2008) investigate whether hedge fund activists simply identify undervalued targets without adding to firms' fundamental values. Using various methodologies, they conclude that the average positive market response to an announcement of fund intervention is not likely driven by the stock picking effect. In our setting, we face a similar problem: hedge funds may simply pick target firms that were already experiencing increases in tax avoidance. Presumably, these target firms might continue the trend in tax avoidance even without hedge fund intervention. In previous sections, we show that changes in tax avoidance after hedge fund intervention are related to hedge fund characteristics such as past success and expertise in implementing tax changes. These results are inconsistent with a pure "stock-picking effect," and are more consistent with the "direct effects" of hedge fund activism on tax avoidance. To further strengthen our analysis, in this section, we conduct a trend analysis of tax avoidance prior to hedge fund intervention. If hedge funds simply cherry-pick target firms that are expected to continue to increase their tax avoidance, then we should expect target firms to exhibit an increasing trend for tax avoidance in years before fund intervention. We estimate the following regression to test the trends of tax avoidance prior to hedge fund intervention:

---

[32] We thank Petro Lisowsky for kindly sharing the sheltering score estimates with us.

[33] Even though the use of tax sheltering might be pervasive, sheltering activities are notoriously difficult to detect (e.g., Graham and Tucker 2006). Academic studies on tax sheltering (Desai and Dharmapala 2006; Graham and Tucker 2006; Wilson 2009) usually rely on court documents and press reports to identify tax shelter firms, and the samples tend to be small. For instance, Wilson (2009) identifies only 59 shelter firms between 1975 and 2007.

[34] The univariate event-study analysis shows a slight decrease (about 1.9 percent) in the average industry-adjusted estimated sheltering probability for target firms after the intervention. After controlling for firm characteristics, the changes in the sheltering probabilities become insignificant in multivariate regressions.

[35] Our ability to make inferences is limited by the extent to which these sheltering models capture the profile of the broader set of tax shelter participants. Therefore, this analysis of sheltering activities is preliminary, and we caution readers not to over-interpret our results.

$$\begin{aligned} Tax\ Measure_{i,t} = {} & \beta_0 + \beta_1 TIME_{i,t} + \beta_2 ROE_{i,t} + \beta_3 Leverage_{i,t} + \beta_4 DNOL_{i,t} + \beta_5 \Delta NOL_{i,t} \\ & + \beta_6 Foreign\ Income_{i,t} + \beta_7 PPE_{i,t} + \beta_8 Intangible\ Asset_{i,t} \\ & + \beta_9 Equity\ Income_{i,t} + \beta_{10} MTB_{i,t-1} + \beta_{11} Size_{i,t-1} + Industry\ Dummies \\ & + \varepsilon_{i,t}, \end{aligned} \tag{3}$$

where *TIME* measures the number of years prior to the Event Year 0 (e.g., −10 to −1), and all other variables are as previously defined in Equation (1). For robustness, we examine several different pre-intervention event windows (untabulated): Years [−10, −1], Years [−5, −1], and Years [−3, −1], respectively. We find significantly positive coefficients on *TIME* for the ETR measures regardless of the event window length we use. For the BTD measures, the coefficients are either zero or negative, and mostly significant. Focusing on the period of [−5,−1], the coefficients on *TIME* for the *Current ETR*, *Cash ETR*, *MP_BTD*, and *DD_BTD* measures are 0.014, 0.017, −0.011, and −0.007, respectively, with all coefficients being significant.[36] The positive coefficients for the ETR measures and the negative coefficients for the BTD measures imply that, on average, the target firms were experiencing decreases in tax avoidance prior to hedge fund intervention. We conduct the same analyses for the matched control firms and do not find similar trends. The finding that the target firms do not continue the decrease in the levels of tax avoidance, but instead increase their levels of tax avoidance after hedge fund intervention, provides additional evidence on a direct effect of hedge fund intervention.

Other Robustness Checks

Desai and Dharmapala (2009) find that tax avoidance is positively associated with firm value when levels of institutional ownership are high, and McGuire et al. (2012) show that auditor expertise can affect a firm's tax avoidance. In unreported analyses, we also control for potential changes in external monitoring by institutional investors and auditors around hedge fund intervention. Specifically, we include the level of institutional ownership and a dummy variable that equals 1 if the target firm used a Big 6 auditor for the period. Our results are robust to these additional controls.

To address the possibility that our results are driven by time-invariant unobservable factors, we include firm-level fixed-effects in Equation (1) and Table 5. We find the results are similar to our original results.

Finally, to mitigate survivorship bias, we use the event window [−1, +2] in our tabulated analyses. One potential limitation with this approach arises from possible changes in tax strategy in the period prior to the intervention, as firm management may suspect a future activism event. To control for this possibility, in untabulated tests, we extend the event window from Years [−1, +2] to Years [−2, +2] and our conclusions remain similar.

---

[36] These untabulated results are available upon request.

VI. DISCUSSION AND CONCLUSION

We extend the tax avoidance literature by examining the impact of an increasingly important class of shareholders—activist hedge funds on corporate tax avoidance. A main goal for hedge fund activists is to identify under-performing firms and adopt intervention and monitoring activities to improve the target firms' value. We propose that taxes can be an important consideration for hedge fund activists when they push target firms for value improvements, and that hedge fund activists' effective monitoring of effort-averse firm managers would improve the target firms' tax planning. Using propensity score matching to construct a control sample, we find that prior to hedge fund intervention, our target firms exhibit significantly lower tax avoidance than their control firms, as measured by both effective tax rates (ETRs) and book-tax differences (BTDs). In addition, we find the target firms experience significant increases in tax avoidance following activist funds' intervention.

An important concern for our research is that increases in tax avoidance may not come directly from hedge fund activists' influence on corporate tax planning, but could arise indirectly from other corporate changes (e.g., operating performance, leverage, and investment decisions) induced by the activism. To control for these indirect effects, we conduct several analyses. We first identify control samples matched on target firms' changes in operating performance, leverage, PPE, and intangible assets, and we find these control firms do not exhibit similar increases in tax avoidance as target firms do. We then use multivariate models with controls for a comprehensive set of potential tax determinants variables suggested in prior literature. To control for selection bias and market-wide changes of tax avoidance, we adjust values of all variables in our study by those of control firms identified through propensity score matching. We find consistent results under all these empirical methods. In addition, we find that increases in tax avoidance are associated with hedge funds' prior track record of implementing tax changes, and their interest and knowledge in tax planning as indicated in their SEC filings. Taken as a whole, the results suggest that our findings of improvements in tax avoidance in target firms are likely due to direct effects of hedge fund intervention.

One limitation of our study is that while we find robust support for increases in tax avoidance following hedge fund intervention events, we do not explicitly identify the tax mechanism underlying the changes. Unraveling the "black box" of tax strategies used to improve tax efficiency is difficult, if not impossible. This empirical challenge leads the most recent review on the tax literature to conclude that "the field cannot explain the variation in tax avoidance very well" (Hanlon and Heitzman 2010). While we provide anecdotal evidence on some specific tax strategies suggested by hedge fund activists in public filings, firms generally refrain from disclosing their tax mechanisms in detail, possibly out of concern with drawing the IRS's attention. Hence, future studies might seek to identify these specific tax strategies by using alternative methodologies, such as conducting surveys of hedge fund activists.

APPENDIX A

ANECDOTAL EVIDENCE ON HEDGE FUND ACTIVISTS TARGETING CORPORATE TAX-PLANNING EFFICIENCY

Lawndale Capital Management vs. Westmore Land Coal Co

In September, 1996, hedge fund activist, Lawndale Capital Management Inc., in its Schedule 13D filing against its target firm, Westmore Land Coal Co, disclosed that it had discussed with the company's management and board of directors about strategies to maximize shareholder value. The discussion included issues on using the company's net operating loss and tax carryforwards for tax benefits.

Source: http://www.sec.gov/Archives/edgar/data/106455/0000935836-96-000034.txt

Third Point vs. Cypress Semiconductor

In August 2007, hedge fund activist Third Point LLC acquired more than 5.1 percent stake at Cypress Semiconductor and demanded the company address its undervaluation quickly.

Specifically, Third Point LLC insisted that there are tax-efficient ways to expedite the process of selling off Cypress Semiconductor's stake in Sunpower, and the company should immediately explore them.

Source: http://www.secinvestor.com/2007/08/10/Cypress+50+Undervalued+CY.aspx

New Mountain Ventures vs. National Fuel Gas

In October 2007, hedge fund activist New Mountain Ventures stated that it plans to nominate its own slate of directors for the board of its target firm, National Fuel Gas. One of New Mountain Ventures' demands for National Fuel Gas was to "change the ownership structure of some of its business in a way that would cut its tax bill."

Source: http://www.highbeam.com/doc/1P2-21663005.html

Greenlight Capital vs. MI Developments

In April 2008, hedge fund activist Greenlight Capital, Inc. publicly announces that it is not in favor of the Reorganization Proposal that its target firm, MI Developments, Inc. (MID), received from entities affiliated with Mr. Frank Stronach and intends to vote against it. One major concern for Greenlight Capital, Inc. about this reorganization is the tax consequence. Specifically, Greenlight Capital, Inc. stated, "The Term Sheet does not disclose the tax effects of the transaction on any of the parties. The Reorganization Proposal presents the following tax issues that should be evaluated, quantified and disclosed both as to the benefit to Mr. Stronach and as to the cost to MID and MID shareholders." Greenlight Capital, Inc. discussed the tax issues in detail, including issues on loss carryforwards, tax attributes of debt (historic tax basis), taxable foreign gains, capital gain taxes, Canadian non-resident withholding taxes, etc.

APPENDIX B
VARIABLE DEFINITIONS

Current ETR = current effective tax rate, which equals total income tax expense (#16) minus deferred income tax expense (#50), divided by pretax net income (#170) minus special items (#17) in year *t*. We truncate the values at 0 and 1;

Cash ETR = cash effective tax rate, which equals cash taxes paid (#317) divided by pretax net income (#170) minus special items (#17) in year *t*. We truncate the values at 0 and 1;

MP_BTD = Manzon and Plesko (2002) book-tax difference, which equals U.S. domestic income (#272) minus U.S. domestic taxable income minus state income taxes (#173) minus other income taxes (#211) minus equity in earnings (#55), scaled by lagged assets (#6). U.S. domestic taxable income is estimated as the current federal tax expense (#63) divided by the statutory maximum corporate tax rate;

DD_BTD = Desai and Dharmapala (2006) residual book-tax difference, which equals the residual from the following firm fixed-effect regression: $BT_{i,t} = \beta_1 TA_{i,t} + \mu_i + \varepsilon_{i,t}$, where *BT* is the Manzon-Plesko book-tax difference and *TA* is total accruals measured using the cash flow method per Hribar and Collins (2002). Both variables are scaled by lagged total assets and are winsorized at 1 percent and 99 percent levels for regression purposes;

Activists' Experience = number of intervention events initiated by the hedge fund activist during the past five years. (*Activists' Experience* is divided by 100 for exposition);
Tax Avoidance Changes in Past Activist Events = average changes in tax avoidance in the firms targeted by the hedge fund activist during the past five years;
Activist Exhibiting Tax Interest or Knowledge = indicator variable if the hedge fund activist has exhibited tax interest or knowledge in one of her 13D or 13D/A filings during the sample period;
TIME = number of years prior to the Event Year 0 (e.g., −10 to −1);
Dummy for Year $t = 1$ if the current year is the Event Year t, with Year 0 being the year in which hedge fund activism is initiated, 0 otherwise;
ROE = return on equity, measured as operating income (#170 – #192), scaled by lagged book value of equity (#60);
Leverage = long-term debt (#9), scaled by lagged assets (#6);
Dummy for Positive Lagged NOL (*DNOL*) = indicator variable coded as 1 if loss carryforward (#52) is positive at the beginning of the year;
Δ*NOL* = change in loss carryforward (#52), scaled by lagged assets (#6);
Foreign Income = foreign income (#273), scaled by lagged assets (#6);
PPE = property, plant, and equipment (#8), scaled by lagged assets (#6);
Intangible Asset = intangible assets (#33), scaled by lagged assets (#6);
Equity Income = equity income in earnings (#55), scaled by lagged assets (#6);
Lagged Market-to-Book = market-to-book ratio at the beginning of the year, measured as market value of equity (#199 × #25), and scaled by book value of equity (#60); and
Lagged Size = natural logarithm of market value of equity (#199 × #25) at the beginning of the year.

Analyst Initiations of Coverage and Stock Return Synchronicity

Steven S. Crawford
Rice University

Darren T. Roulstone
The Ohio State University

Eric C. So
Stanford University

ABSTRACT: We examine how the information produced by analysts when they *initiate* coverage contributes to the mix of firm-specific, industry-, and market-wide information available about the firm. We hypothesize that the first analyst to initiate coverage provides low-cost market and industry information allowing him/her to follow more stocks, whereas subsequent analysts provide firm-specific information to distinguish themselves from existing analysts. We use stock return synchronicity to measure the mix of information available about a firm, with higher synchronicity indicating more industry and market information. Coverage initiations of firms with no prior analyst coverage increase synchronicity, suggesting that analysts produce industry- and market-wide information. In contrast, analysts initiating coverage on firms with existing coverage appear to focus on producing firm-specific information as these initiations lead to reduced synchronicity. Together, our findings indicate that the type of information that analysts produce at initiation depends on the information provided by other analysts.

Keywords: *stock return synchronicity; financial analysts; analyst initiations.*

I. INTRODUCTION

A commonly held belief is that analysts primarily contribute firm-specific information to the market, which is logical given that much of the information produced by analysts relates directly to the firm in question, e.g., earnings forecasts and stock-specific recommendations. The belief is also supported by many studies that document associations between the information produced by analysts and market-adjusted firm returns (e.g., Schipper 1991; Ramnath et al. 2008). However, analysts also provide industry and market information to support their firm-level assessments, and many analysts make explicit recommendations regarding the industry outlook (Asquith et al. 2005; Kadan et al. 2011). Empirical evidence supports the use and importance of market- and industry-level information in analyst reports. For example, Ramnath (2002) shows that analysts revise their earnings forecasts when firms in the same industry make earnings announcements, and Hameed et al. (2010) document that analyst forecast revisions move prices of other firms in the industry. Furthermore, Piotroski and Roulstone (2004) argue that because analysts lack access to inside information (relative to institutions and insiders) they are likely to focus their efforts on collecting and interpreting industry- and market-wide information as it relates to the firms they cover, and their tests provide evidence consistent with these arguments.

In this study, we examine how the information produced by analysts when they *initiate* coverage contributes to the mix of firm-specific and industry- and market-wide information available about the firm, as measured by stock return synchronicity (measured as the R^2 value from a regression of firm returns on market and industry returns). We also explore whether the level of existing analyst coverage at the initiation affects the type of information analysts provide. These innovations provide two important contributions to the literature. First, coverage initiations represent a significant change in the information provided by analysts; thus, more new information is contained in initiation reports than in the reports of analysts engaged in continuing coverage. Evidence of this is found in studies that document abnormal returns around coverage initiations relative to other analyst activity (see Peterson 1987; Branson et al. 1998; Irvine 2003). We add to these studies by identifying how the mixture of firm-, industry-, and market-based information is rebalanced around initiations and thus identify compositional changes to the set of publicly available information that is associated with abnormal returns. Additionally, by examining how changes in coverage affect information, we alleviate concerns that analysts simply choose to follow firms that provide a specific mix of information to investors (see Piotroski and Roulstone 2004).[1]

Second, by conditioning our analysis on the existing level of coverage at the time of an initiation, we provide insight into whether analyst incentives to gather firm versus industry and market information depend on competition from other analysts—an issue that prior studies do not explore. This analysis is particularly important because analysts are thought to erode the informational advantage of insiders and institutions (Frankel and Li 2004). We examine whether this erosion is sensitive to the existing level of coverage.

Understanding analyst incentives to cover firms is important when examining how coverage initiations and competition influence the mix of information available about a firm. Analysts initiate coverage to generate lucrative trading commissions, drum-up investment banking business, and to provide information to important institutional clients (see Irvine 2003). Two important considerations affect the type of information they choose to provide: (1) information-gathering and -processing costs and (2) competition among other analysts. For new initiations (defined as initiations for firms without prior analyst coverage), only the former consideration applies. This implies that analysts will choose to gather and disseminate low-cost information because it allows them to follow a larger set of stocks, and covering more stocks enables analysts to increase trading commissions, attract more investment banking business, and increase their compensation (Groysberg et al. 2011).[2] Gathering market and industry information poses the lowest cost because it does not require access to management or detailed analysis of historical financial statements. While market and industry information is less costly to acquire, it may provide fewer benefits to investors in terms of their ability to make capital allocation decisions *vis-à-vis* firm-specific information. Nevertheless, market and industry information can facilitate investors' capital allocation decisions as it provides investors with important information about how a firm's fundamentals vary with the market or its industry. This is especially true in the case of new initiations because no other analyst-provided information exists. For subsequent initiations (defined as initiations for firms with prior analyst coverage), the decision regarding what type of information to provide is less trivial because analysts also need to concern themselves with competition from other analysts. Thus, subsequent analysts face a greater incentive to provide firm-specific information to distinguish themselves from other analysts already covering the firm.

---

[1] While using a changes specification alleviates concerns that analysts simply choose to follow synchronous firms, our results are still subject to the concern that initiations are predetermined, i.e., variables that lead to changes in coverage could also precipitate changes in synchronicity. We discuss this concern in Sections III and V.

Based on this reasoning, the central hypothesis of our paper is that the first analyst initiating coverage of a firm provides more market and industry information, while subsequent analysts provide more firm-specific information. Consistent with our expectations, we find that analyst initiations of firms with no prior coverage increase the amount of industry and market information being impounded into price, as evidenced by an increase in synchronicity. Initiations of firms with existing coverage appear to decrease synchronicity, consistent with these initiations increasing the amount of firm-specific information flowing into price. Our results suggest that the type of information analysts provide in their initiation reports depends on whether the firm is being followed by other analysts.

Given that analysts choose to initiate coverage on firms, we must address the possibility that initiations are correlated with other events or characteristics that drive changes in stock return synchronicity. In our main tests we include control variables that may be correlated with both an analyst's decision to initiate coverage and changes in the mix of information regarding a given firm. To further address endogeneity concerns, we search for changes in analyst coverage that are plausibly exogenous to the individual firm. Specifically, we examine instances in which brokerage houses drop coverage of entire industry sectors.[3] We find that these "exogenous drops" in coverage are associated with increases in stock return synchronicity, mirroring the decreases in synchronicity associated with initiations at firms with existing coverage. We also use propensity score matching and find our results are robust to this methodology.

We also investigate whether changes in return synchronicity are the result of analyst initiations inducing co-movement among stocks for non-information reasons (see Barberis et al. 2005). We do so by adding the change in trading-volume synchronicity (defined as the extent to which market- and industry-level trading volume explain firm-level trading volume) to our main regressions and showing that our main results still hold. This suggests that analyst initiations change the mix of information available about the firm rather than simply causing stocks to trade in a more synchronous manner.

---

[2] These benefits may come as a result of the analyst "planting the flag" on a stock. Being the first analyst to cover a stock can serve to set the analyst apart from others not only in terms of receiving future brokerage commissions, but also with respect to generating investment banking business. For example, the covered firm may be more likely to develop a professional relationship with the analyst who is the first to provide coverage that may raise the analyst's employer to the top of the list when it comes time for the firm to engage the services of an investment bank.

[3] This methodology is similar in spirit to that in Kelly and Ljungqvist (2012) who examine drops in coverage caused by the closing of brokerage houses.

To sharpen the inferences of our main empirical tests, we also examine alternative measures of the mix of information available regarding a firm. As earnings forecasts are a primary output of analysts' efforts, we examine whether initiations aid in incorporating firm-specific or industry-level earnings surprises into consensus forecasts. Specifically, we show that new initiations are more likely to mitigate the relation between industry earnings innovations and consensus forecast errors, while subsequent initiations are more likely to mitigate the relation between firm-specific earnings innovations and consensus forecast errors. Furthermore, we examine changes in market and industry betas and changes in return kurtosis (Roll 1988). The results with these measures also support our conclusion that the type of information analysts produce at initiation depends critically on the information being provided by other analysts.

The rest of the paper is organized as follows. Section II details prior literature and develops our central hypotheses and Section III discusses the research design. Section IV discusses the findings of our main tests and Section V discusses several robustness checks. Section VI concludes.

II. PRIOR LITERATURE AND HYPOTHESIS DEVELOPMENT

Analysts' Contribution to the Information Environment of the Firm

Piotroski and Roulstone (2004) are among the first to empirically examine the type of information that analysts contribute to the price formation process. They examine the association between stock return synchronicity and the trading activities of analysts, institutions, and insiders. Piotroski and Roulstone (2004) postulate that analysts typically have less access to firm-level information than do insiders and institutions, making them more likely to specialize in obtaining and mapping industry- and market-level information into prices.[4] In their tests, Piotroski and Roulstone (2004) find that analyst coverage is positively related to stock return synchronicity, which is consistent with analysts increasing the amount of market- and industry-level information included in firms' stock prices. The authors argue that the association is a result of analysts facilitating intra-industry information transfers, i.e., analysts use their industry expertise to better interpret and disseminate common information across all firms in an industry.

To provide additional intuition for the Piotroski and Roulstone (2004) results and our main hypothesis, we define industry- and market-level information as encompassing two non-mutually exclusive components: (1) information about the performance of a given industry and the broader macroeconomy and (2) any information that describes how firms' fundamentals covary with market and industry performance. Synchronicity changes whenever new information alters investors' understanding of how the fundamentals of the firm align with the fundamentals of the industry or macroeconomy. This is because the market is better equipped to understand the implications of industry and market news for a firm and incorporate this news into firms' share prices in a timely fashion.

Pushing this argument further, if analysts provide new information that a firm's earnings prospects are heavily tied to the state of the macroeconomy or industry outlook, then investors have increased confidence that upturns (downturns) in market and industry indices signal an increase (decrease) in the value of the firm's future cash flows. Thus, we expect firms' synchronicity to increase, since price movements will exhibit a higher tendency to mirror market and industry indices.

---

[4] This assertion is supported by the tendency of analysts to specialize in a given industry (see Liang et al. 2008). Clement (1999) documents a positive association between forecast accuracy and the degree of analyst specialization.

One example of industry information comes from an initiation report on FiberNet Telecom, a telecommunications company, by an analyst at Merriman, Curhan, and Ford. In the report, the analyst describes how industry trends will affect the firm: "We expect FiberNet to benefit from macro industry trends, including firming pricing and increasing demand, as well as an improved operating structure . . . Similar to other data center companies, FiberNet is currently increasing its prices primarily due to the limited space that it and its competitors have" (Synesael 2006, 2, 4). Note that the analyst points out how FiberNet is similar to competitors and, thus, linking its price to the prices of other firms in the industry, which should increase synchronicity. We interpret this report as conveying industry information because it focuses on industry trends as the primary impetus for changes in FiberNet's performance prospects.

While Piotroski and Roulstone (2004) and others (e.g., Chan and Hameed 2006) show that analyst following is positively correlated with the relative amount of market- and industry-level information in prices, Liu (2011) suggests that the information analysts provide is predominantly firm-specific. Liu (2011) predicts that analysts produce more firm-specific information because its investment value is greater than the value of industry-specific information. To test his prediction, Liu (2011) examines short- and long-window market and industry adjusted returns surrounding analyst recommendation revisions and finds that revisions predominantly affect the firm-specific portion of returns.[5] Liu's (2011) arguments and results are intriguing because they suggest that analysts' incentives to gather firm-specific information will depend on analysts' beliefs about what information is already reflected in prices.[6]

We believe the type of firm-specific information referenced in Liu (2011) may include an analyst's analysis and discussion of novel strategies, products, services, and operations unique to the covered firm. One example of this type of information comes from a report by Rodman & Renshaw who initiated subsequent coverage on Conor Medsystems, a manufacturer of "CoStar" medical stents. In the report, the analyst provides a detailed description of Conor's unique product offerings: "Unlike conventional drug-eluting stents, the CoStar has unique laser drilled reservoirs that can be filled with multiple drug entities and then top-coated with a biodegradable polymer . . . We believe the CoStar can gain at least 8–10 percent market share in 2008, based on the strong clinical results so far" (Kalia 2005, 2). We interpret this report as conveying firm-specific information because it focuses on product developments unique to Conor Medsystems as the primary impetus for changes in the firm's fundamentals. This type of firm-specific information will tend to move the firm's price but have little impact on other firms and, thus, will reduce synchronicity.

Analyst Initiations

Our main empirical tests examine how coverage initiations affect stock return synchronicity. Initiations provide us with a powerful setting in which to test how analyst activity contributes to the flow of information because initiations likely contain more new information than continuing coverage reports. Several studies make this conjecture and then go on to show that initiations result in short-window, positive returns (see Peterson 1987; Branson et al. 1998; Irvine 2003; Demiroglu and Ryngaert 2010). Also, Demiroglu and Ryngaert (2010) document that new initiations of neglected stocks (those without any prior coverage) are particularly distinctive events. Finally, Schutte and Unlu (2009) show initiations defined at the firm-year level are associated with a decline in a measure of the noise in security prices. Although the results of these papers suggest that initiation events are notably different than continuing analyst coverage, they do not provide any evidence that the type of information contained in initiation reports is more firm-specific than it is market- and industry-related.

---

[5] We note that our findings and the results in Liu (2011) both document that firm returns are predominantly driven by firm-specific information. Our focus is on how the mix of information in returns shifts with analyst activity and how these shifts are affected by the level of analyst coverage.

[6] In determining our research design, we considered using an approach similar to Liu's (2011). However, his methodology relies on estimating market and industry betas prior to recommendation revisions in order to calculate the firm, industry, and market components of returns. Because initiations shift market and industry betas (see Section V), his approach is not well suited for our setting. In addition, short-window returns around initiations reflect not only the information provided by analysts, but also the market's perception of the benefits that accompany new coverage (e.g., increased liquidity as in Irvine [2003]). Furthermore, the market's assessment of these benefits is likely to be different for firms with little or no coverage than it is for firms with a large analyst following. In fact, we know from Irvine (2003) and others that short-window returns surrounding initiations are more positive for initiations with less analyst coverage as new analyst coverage is generally viewed as a favorable event for these firms.

III. SAMPLE AND RESEARCH DESIGN

In this section, we describe our sample of analyst initiations and our synchronicity measure. We also formally specify our empirical tests.

Initiation Sample

We identify analyst initiations following the methodology of Irvine (2003) and Irvine et al. (2007).[7] We collect analyst recommendations on U.S. stocks from the I/B/E/S detail recommendation file. We count a recommendation as an initiation if it is the first time a given broker is associated with a particular firm on the I/B/E/S tape. We also require that it be the first time the analyst has covered the firm. This ensures that recommendations an analyst makes about a firm after the analyst moves from one brokerage house to another are not counted as initiations if the analyst covered the stock before switching employers. We also eliminate any initiations of coverage for IPO firms by deleting initiations that occur within three months of a firm's appearance on CRSP, our source of price and return data.

Occasionally, I/B/E/S adds brokerage firms to its coverage universe. Typically, these additions reflect a broadening of coverage by I/B/E/S rather than a response to the creation of a new brokerage firm. To ensure that we do not count simple database additions as initiations, we begin our sample in 1996 instead of 1994 when I/B/E/S first began gathering recommendations. We do so because coverage increased rapidly in the first several months of the I/B/E/S recommendation file. Furthermore, we eliminate initiations for brokerage firms that have not appeared in the I/B/E/S recommendation detail file for at least six months. After implementing these screens to identify initiations, we are left with 60,021 firm-months with at least one initiation from 1996 to 2006. We also require initiation firms to have the necessary data to compute the variables used in our study. This results in a sample of 39,855 firm-months with at least one initiation.[8] Table 1 shows the number of initiations by year. The number of initiation observations fluctuates over the sample period, with a high in 1998 of 5,069 and a low of 2,827 in 2006.

To determine whether the effects of coverage initiations on synchronicity vary based on the level of existing coverage at the time of the initiation, we measure the level of existing analyst coverage for each of our initiations. Specifically, we distinguish between initiations with no prior coverage (new initiations) and those with prior coverage (subsequent initiations). Initiations that

---

[7] Irvine (2003) validates his sample of initiations by searching the Dow Jones News Service (DJNS) for press coverage of the initiations. All but two of the initiations identified by DJNS as initiations are initiations in his sample. Furthermore, the initiation dates, as recorded by DJNS, match the initiation dates on I/B/E/S in all but three cases.

[8] We report the number of initiations at the firm-month level because we examine how synchronicity changes around a given month. The number of unique initiation events in our sample is 44,707. Our sample size is smaller than the sample in Ertimur et al. (2011) because of data restrictions.

TABLE 1

Sample of Analyst Initiations

Panel A: Number of Initiations Each Year

	$INITIATION_{i,t}$	$INITIATION\_NEW_{i,t}$	$INITIATION\_SUB_{i,t}$
1996	3,877	365	3,512
1997	4,068	289	3,779
1998	5,069	236	4,833
1999	4,172	195	3,977
2000	3,943	214	3,729
2001	3,677	139	3,538
2002	3,221	198	3,023
2003	2,887	185	2,702
2004	3,119	175	2,944
2005	2,995	178	2,817
2006	2,827	128	2,699
Total	39,855	2,302	37,553

Panel B: Number of Analysts Initiating Coverage at the Initiation

	$INITIATION_{i,t}$	$INITIATION\_NEW_{i,t}$	$INITIATION\_SUB_{i,t}$
1	35,690	2,120	33,570
2	3,599	149	3,450
3	475	24	451
4	69	6	63
5	18	3	15
6	2	0	2
7	1	0	1
9	1	0	1

Panel C: Recommendation Level

	$INITIATION_{i,t}$	$INITIATION\_NEW_{i,t}$	$INITIATION\_SUB_{i,t}$
1 = Strong Buy	14,009	1,021	12,988
2 = Buy	15,060	932	14,128
3 = Hold	9,966	327	9,639
4 = Sell	499	14	485
5 = Strong Sell	321	8	313

This table presents the number of firm-months with coverage initiations ($INITIATION_{i,t}$) used in our primary tests as well as the breakdown between firm-months with new initiations ($INITIATION\_NEW_{i,t}$) and subsequent initiations ($INITIATION\_SUB_{i,t}$). See Appendix A for detailed variable definitions.

Panel A shows the number of firm-months with initiations in each year.

Panel B shows the number of analysts initiating coverage for each initiation.

Panel C shows the I/B/E/S recommendation associated with each initiation. The recommendation code is an integer between 1 and 5 where 1 = Strong Buy and 5 = Strong Sell.

occur at firms with (no) existing coverage are denoted by the indicator variable ($INITIATION\_NEW_{i,t}$) $INITIATION\_SUB_{i,t}$.

Table 1 shows the number of initiations based on the level of existing coverage; new initiations make up about 5 percent of all initiations. In Table 1, we also document occasions during which multiple analysts initiate coverage on a firm in the same month. While the vast majority of initiations are made by a single analyst, approximately 10 percent of the sample is comprised of initiations by more than one analyst. Finally, Table 1 shows the recommendation level associated with the initiations (1 = Strong Buy, 5 = Strong Sell). Initiation recommendations are overwhelmingly favorable, especially for new initiations. The proportion of strong buy recommendations for new initiations is 44 percent, while subsequent initiations are associated with a strong buy 35 percent of the time.

Synchronicity Literature

Roll (1988) was the first to formalize the notion that stock return synchronicity, the association between a firm's stock returns and market and industry returns, is negatively associated with the amount of firm-specific information being impounded into individual stock prices. Since Roll's (1988) work, several studies have provided empirical support for his interpretation of synchronicity. For example, Durnev et al. (2004) show that lower synchronicity is associated with the efficient allocation of capital within U.S. capital markets. They argue this relation is a result of firm-specific information being impounded into prices, allowing for greater monitoring and reduced information asymmetry between insiders and outsiders. Many papers interpret synchronicity similarly (e.g., Morck et al. 2000; Wurgler 2000; Durnev et al. 2003; Ferreira and Laux 2007). Alternatively, some papers argue and find evidence that low synchronicity or high firm-specific volatility is a measure of noise (e.g., West 1988; Kelly 2007; Teoh et al. 2008). Given the debate over synchronicity as a measure of the mix of information available about a given firm, our empirical analyses are joint tests of how analyst initiations contribute to the information environment of the firm and our interpretation of stock return synchronicity.[9] To support the results using synchronicity we also examine the relation between analyst initiations and three additional measures of information flow: the association between forecast errors and firm- and industry-components of earnings, market and industry betas, and return kurtosis (see Section V).

Measurement of Stock Return Synchronicity

We use a measure of stock return synchronicity that is similar to measures found in the prior literature. However, our empirical focus is different in that we examine changes in synchronicity around an analyst initiation. Given this focus, we measure synchronicity and changes in synchronicity using daily returns over a relatively short time period.

For each calendar month, we estimate a firm-level measure of return synchronicity. Specifically, for each firm-month observation, we regress daily returns on the value-weighted market return and the value-weighted two-digit SIC industry return, or:

$$RET_{i,t} = \alpha + \beta_1 MARET_{i,t} + \beta_2 INDRET_{i,t} + \varepsilon_{i,t}. \tag{1}$$

---

[9] We interpret increases in return synchronicity as reflecting a decrease in the fraction of firms' returns that are explained by contemporaneous changes in the market and industry indices. The positive relation between new initiations and synchronicity suggests that analysts tend to provide information about how the fundamentals of the market or industry are likely to covary positively with the fundamentals of the covered firm. An additional and non-mutually exclusive interpretation is that new initiations increase synchronicity by reducing estimation risk associated with market and industry betas. We examine this interpretation in Section V, where we measure changes in market and industry betas around initiations.

The industry return ($INDRET_{i,t}$) for a specific day t, is created using all firms with the same two-digit SIC code, with firm i's daily return omitted. $INDRET_{i,t}$ is the value-weighted average of these firms' day t returns. We estimate this regression using daily returns from the past three months for each firm-month, with a minimum of 50 daily observations. For example, IBM's synchronicity measure for May 2000 is estimated using daily returns from March, April, and May 2000. All stock return data are gathered through CRSP. Following the definition in Morck et al. (2000), we define synchronicity as:

$$SYNCH_{i,t} = \log\left(\frac{R^2}{1-R^2}\right). \tag{2}$$

where R^2 is the coefficient of determination from the estimation of Equation (1).[10] The log transformation of R^2 creates an unbounded continuous variable out of a variable originally bounded by 0 and 1. *SYNCH* is measured for each firm-month in the sample. By construction, high values of *SYNCH* indicate firms whose stock returns are closely tied to and vary strongly with market and industry returns and whose returns reflect relatively less firm-specific information.

Empirical Tests

The Effect of Initiations on Synchronicity

To determine if analyst initiations increase the amount of firm-specific or market- and industry-wide information impounded into prices we estimate the following equation using OLS:

$$\begin{aligned}\Delta SYNCH_{i,t} = {} & \alpha_0 + \beta_1 INITIATION_{i,t} + \beta_2 INITIATION_{i,t} * LNUM_{i,t-1} + \beta_3 LNUM_{i,t-1} \\ & + \beta_4 \Delta LMVE_{i,t} + \beta_5 \Delta INST_{i,t} + \beta_6 \Delta TURN_{i,t} + \beta_7 RET\_12_{i,t} + \beta_8 ISSUE\_12_{i,t} \\ & + \beta_9 REPORT_{i,t-1} + \beta_{10} GUIDE\_6_{i,t} + \beta_{11} LBM_{i,t-1} + \beta_{12} STDROA_{i,t} \\ & + \beta_{13} REG_{i,t} + \sum \alpha_i FIRM_i + \varepsilon_{i,t}.\end{aligned} \tag{3}$$

In all of our analyses, we provide standard errors corrected for cross-sectional and serial correlation by clustering at the industry (two-digit SIC) level. Our OLS estimations of Equation (3) also include firm fixed effects.

We define the variables as follows: $\Delta SYNCH_{i,t}$ is the change in synchronicity, defined as $SYNCH_{i,t+3} - SYNCH_{i,t-1}$.[11] $LNUM_{i,t-1}$ is the natural log of 1 plus the number of analysts covering firm i in month $t-1$. The estimated coefficients on $INITIATION_{i,t}$ and $INITIATION_{i,t} * LNUM_{i,t-1}$ are of primary interest in Equation (3). The coefficient on $INITIATION_{i,t}$ reveals how synchronicity responds to initiations, and the interaction term captures whether the type of information provided in initiation reports depends on the existing level of coverage. We define the remaining variables in Appendix A.

In addition to Equation (3), we introduce an alternative approach to estimating how the level of existing coverage can affect the relation between initiations and changes in synchronicity as follows:

$$\begin{aligned}\Delta SYNCH_{i,t} = {} & \rho_0 + \gamma_1 INITIATION\_NEW_{i,t} + \gamma_2 INITIATION\_SUB_{i,t} + \gamma_3 DROP_{i,t-1} \\ & + \gamma_4 DROP\_ZERO_{i,t-1} + \gamma_5 \Delta LMVE_{i,t} + \gamma_6 \Delta INST_{i,t} + \gamma_7 \Delta TURN_{i,t} \\ & + \gamma_8 RET\_12_{i,t} + \gamma_9 ISSUE\_12_{i,t} + \gamma_{10} REPORT_{i,t-1} + \gamma_{11} GUIDE\_6_{i,t} \\ & + \gamma_{12} LBM_{i,t-1} + \gamma_{13} STDROA_{i,t} + \gamma_{14} REG_{i,t} + \sum \rho_i FIRM_i + \varepsilon_{i,t}.\end{aligned} \tag{4}$$

---

[10] We use the adjusted R^2 in all of our empirical tests. We follow the literature and trim negative adjusted R^2 numbers at 0.0001.

[11] We define the change in synchronicity using two, non-overlapping measures of synchronicity. $SYNCH_{i,t+3}$ uses data from the three months following month t while $SYNCH_{i,t-1}$ uses data from the three months preceding month t.

In Equation (4) we define four new variables that take the place of $LNUM_{i,t-1}$ in Equation (3). If analysts contribute relatively more industry- and market-related (firm-specific) information about the firms they cover, then the estimated coefficients on $INITIATION\_NEW_{i,t}$ and $INITIATION\_SUB_{i,t}$ should be positive (negative). For completeness, we also define two variables related to decreases in analyst coverage: $DROP_{i,t}$ is an indicator variable set equal to 1 if the level of analyst coverage declines from month $t-1$ to t. $DROP\_ZERO_{i,t}$ is an indicator variable set equal to 1 if analyst coverage is non-zero in month $t-1$ and becomes 0 in month t. We include these variables to examine whether the loss of coverage provides insight into the type of information provided by analysts.[12]

The remaining variables in Equations (3) and (4) are controls. Fundamentally, variables should be included if they affect the type of information flowing into prices. Because we are not aware of prior studies that examine the determinants of shifts in stock return synchronicity, we base the variables included in our model on intuition and the results of related studies (see Bhushan 1989; O'Brien and Bhushan 1990). Additionally, we attempt to control for variables tied to analyst incentives that may also influence synchronicity. $\Delta LMVE_{i,t}$ is the change in the natural log of market value, defined as $LMVE_{i,t+1} - LMVE_{i,t-1}$. We include $\Delta LMVE_{i,t}$ because changes in size are likely to be associated with various dimensions of the firm's information environment, including media exposure and the overall level of investor interest. $\Delta INST_{i,t}$ is the average value of $INST$ in months $t+1$ to $t+6$, less the average value of $INST$ in months $t-1$ to $t-6$. We include variables related to institutional holdings because of their association with synchronicity, as documented in Piotroski and Roulstone (2004); in addition, analysts' initiations may be correlated with changes in institutional ownership. $TURN_{i,t}$ is the number of shares traded in month t divided by the number of shares outstanding as identified in CRSP. $\Delta TURN_{i,t}$ is the average value of $TURN$ in months $t+1$ to $t+6$, less the average value of $TURN$ in months $t-1$ to $t-6$. As discussed in Section IV, we include share turnover to control for changes in synchronicity that are driven by increased investor awareness that is unrelated to the type of information in analysts' reports. $RET\_12_{i,t}$ is the market-adjusted return on the firm's stock from $t-12$ to $t-1$, as measured by CRSP. We control for past returns as a summary measure of the information being released about the firm over the prior year. Further, analysts prefer to initiate coverage on stocks that have performed well (McNichols and O'Brien 1997). $ISSUE\_12_{i,t}$ is an indicator variable set equal to 1 if the firm issued equity in the past 12 months, 0 otherwise, which we include because issuing firms may be undergoing changes that affect how they relate to other firms in the industry and market. $REPORT_{i,t-1}$ is an indicator variable set equal to 1 if the firm reported earnings in month $t-1$, 0 otherwise. $GUIDE\_6_{i,t}$ is an indicator variable set equal to 1 if the firm issued earnings guidance within the last six months. We gather earnings release dates from Compustat and earnings guidance dates from First Call. We include $REPORT_{i,t-1}$ and $GUIDE\_6_{i,t}$ because they are information events that may affect synchronicity.[13] $LBM_{i,t-1}$ is the natural log of the book-to-market ratio in month $t-1$. $STDROA_{i,t}$ is the standard deviation of return on assets (ROA) measured over the current and previous four quarters. We include these two variables because analysts have been shown to prefer growth firms and firms with less volatile earnings. $REG_{i,t}$ is an indicator variable for financial services or utilities, which we include because firms in regulated industries are subject to common constraints on their operations, making it more likely that their returns move together.

---

[12] Dropped coverage may or may not have the same effect on synchronicity as initiations. On the one hand, when an analyst drops coverage there will be a decrease in the amount of information available about a firm, which would suggest that synchronicity changes accordingly. On the other hand, the analyst's recent reports and forecasts are not removed from the information set available to investors, so the corresponding change in synchronicity could happen over a long period of time as the analyst's information becomes stale and less relevant to current circumstances. Ultimately, the issue of whether drops affect synchronicity is an empirical question.

[13] Barron et al. (2002) show that earnings announcements trigger analyst information production. Also, Stickel (1989) finds that analysts supply more forecasts following large, negative earnings surprises.

TABLE 2

Descriptive Statistics for the Sample of Firm-Month Observations Available between Fiscal Years 1996 and 2006

IV. EMPIRICAL RESULTS

Univariate Statistics

Table 2 presents descriptive statistics for the variables we use in the study. For comparison purposes, we report the statistics for the raw R^2 values although we do not use this measure in any of our empirical tests. The average R^2 value is about 11.05 percent.[14] The average values of $SYNCH_{i,t}$ and $\Delta SYNCH_{i,t}$ are −4.4808 and 0.0472. Evaluated at the mean of R^2, this change in synchronicity represents a 0.47 percentage point increase in R^2 from 11.05 percent to 11.52 percent. Initiations occur in roughly 6 percent of the firm-month observations indicating that they are relatively infrequent events. Finally, a significant portion of our firm-months have no analyst coverage, as reflected in the first quartile of $NUM_{i,t-1}$ being 0.

---

[14] Morck et al. (2000) report an average R^2 in the U.S. of approximately two percent. Piotroski and Roulstone (2004) report an R^2 of over 19 percent in their sample. Our estimate falls between these two figures, which is likely due to (1) Piotroski and Roulstone (2004) including both current and lagged market and industry returns as explanatory variables in their synchronicity regressions; and (2) Morck et al. (2000) including only the market return in their regressions.

Table 2 also displays summary statistics for the control variables in the study. The median value of $LMVE_{i,t-1}$ is 11.97, which corresponds to a market value of approximately $157 million. Second, institutions own 31 percent of the average firm's shares. Third, on average, returns are positive in our sample, and only 4.6 percent of the firms in the sample are from regulated industries.

In untabulated results, we find that $\Delta SYNCH_{i,t}$ is not strongly correlated (all correlations with $\Delta SYNCH_{i,t}$ are less than $|0.05|$) with the independent variables included in Equations (3) and (4) or the other variables used in the analysis. Further, a strong positive (negative) relation exists between $LNUM_{i,t-1}$ and $INITIATION\_SUB_{i,t}$ ($INITIATION\_NEW_{i,t}$) because only firms with (without) coverage can have a subsequent (new) initiation.

The Impact of Initiations on Changes in Synchronicity

Table 3 reports the results of estimating Equations (3) and (4). The coefficient on $INITIATION_{i,t}$ reported in column (1) is –0.0484, suggesting that an initiation reduces synchronicity. The results in column (2) indicate that the negative effect of an initiation increases in the level of existing coverage. In fact, the effect of an initiation on changes in synchronicity is positive when prior coverage is 0. The results from estimating Equation (4) corroborate the preceding findings. Column (3) of Table 3 shows the estimated coefficient on $INITIATION\_SUB_{i,t}$ is negative and significant, while the coefficient on $INITIATION\_NEW_{i,t}$ is positive and significant. The absolute magnitude of the coefficient on $INITIATION\_NEW_{i,t}$ is approximately three times that of the coefficient on $INITIATION\_SUB_{i,t}$, suggesting that the absolute magnitudes of the impact on synchronicity is greater for first-time initiations than subsequent initiations. Initiations have significant economic effects with a new initiation producing a 2.38 percentage point shift in the average R^2 value from 11.05 percent to 13.43 percent. Subsequent initiations result in a downward shift in the R^2 value of 0.642 percentage points. Column (4) shows that decreases in coverage do not appear to affect synchronicity.

We interpret the results in Table 3 as indicating first that analysts initiating coverage at firms with no prior coverage provide relatively more industry- and market-related information about these firms as evidenced by the increase in synchronicity around the initiation. This is consistent with analysts gathering information that is relatively inexpensive to acquire but potentially valuable for investors seeking to place a newly covered firm in the context of its market and industry. Second, analysts initiating coverage at firms with existing coverage provide relatively more firm-specific information about the covered firm. These results are consistent with analysts only initiating coverage if they have a relevant piece of firm-specific information to share with investors since industry- and market-related information has already been provided by other analysts. These results suggest that the type of information analysts produce in their initiation reports depends on the information that other analysts already provide.[15]

---

[15] We also examine whether the effects of initiations vary across analyst and recommendation characteristics. We identify seven characteristics and interact them separately with $INITIATION\_NEW_{i,t}$ and $INITIATION\_SUB_{i,t}$ in Equation (4). The characteristics are as follows: (1) the level of the I/B/E/S recommendation code (an integer between 1 and 5 where 1 = Strong Buy and 5 = Strong Sell); (2) analyst experience measured as the number of months since the analyst appeared in I/B/E/S; (3) analyst employer resources captured by whether the analyst is employed at a brokerage in the largest size decile of brokerages (measured by number of analysts); (4) analyst specialization in a given industry; (5) whether an analyst initiates coverage on a firm in his industry of specialization; (6) the number of firms already covered by the analyst; (7) all-star analysts, as ranked by *Institutional Investor* magazine. Our untabulated results show little effect from these analyst-characteristic variables. Further, untabulated tests reflect no evidence that multiple initiations have a differential effect on synchronicity. Finally, we examine whether the intensity of coverage in a given industry affects how initiations impact synchronicity and find that initiations appear to have a uniform effect on synchronicity regardless of the intensity of coverage in a particular industry.

All variables are defined in Appendix A. t-statistics (in parentheses) are based on standard errors that are robust to heteroscedasticity and correlation across observations from the same two-digit SIC industry.

The coefficients on the control variables in Table 3 indicate that increases in the percentage of shares held by institutions, positive past returns, and the release of financial information increase synchronicity, while an increase in share turnover and the issuance of equity decrease synchronicity.

V. ROBUSTNESS CHECKS

This section reports checks on the robustness of the main empirical findings of Section IV.

Endogeneity

Work by McNichols and O'Brien (1997) and the theoretical model of Hayes (1998) provide evidence of endogenous coverage decisions. To the extent that expected changes in return synchronicity endogenously determine analyst coverage decisions, our coefficient estimates may be biased. To mitigate these concerns we examine instances in which a brokerage firm appears to exogenously drop coverage of an entire sector.

While we are unable to rule out the possibility that sector terminations are also endogenous, sector terminations are usually associated with brokerage firms shifting their focus across industries, brokerage closures, or changes in analyst coverage associated with brokerage firm mergers and acquisitions (Hong and Kacperczyk 2010). Using the I/B/E/S Detail Estimates file, we identify sector terminations as instances in which a brokerage firm (1) provides coverage of at least ten firms within a given four-digit SIC code and (2) ceases providing coverage on at least 75 percent of these firms in a given quarter, and (3) does not resume coverage within the next two quarters. This methodology identifies 1,643 firm-quarters of dropped coverage attributed to sector terminations. The resulting variable, $EXOG_{i,q}$, equals 1 in the presence of an exogenous drop in quarter q, and 0 otherwise. We treat all other sector drops failing to meet the above three criteria as endogenous.

Since we use the absence of analysts' forecasts within a two-quarter span as an indication of dropped coverage, drops in analyst coverage are identified at the quarterly level. Thus, to investigate the impact of exogenous changes in analyst coverage on return synchronicity, our main dependent variable is the difference in return synchronicity in the three months following a given quarter versus the three months prior to the quarter. Analogous to our main dependent variable above, we define $\Delta SYNCH_{i,q}$ as $SYNCH_{i,q+1} - SYNCH_{i,q-1}$, where the time subscript denotes the quarter of measurement.

In columns (1) and (2) of Table 4, the coefficient on $EXOG_{i,q}$ is positive and significant suggesting that reductions in analyst coverage increase return synchronicity. These results are consistent with those in Table 3 where subsequent initiations are associated with decreases in return synchronicity. Overall, to the extent that sector drops reflect exogenous changes in analyst coverage, the results of this section provide supporting evidence for our main findings.

As an alternative approach to addressing endogeneity concerns, we employ propensity score matching to match firm-months with initiations to firm-months without initiations that are similar along multiple observable dimensions (Rosenbaum and Rubin 1983). Within each calendar month, we estimate the likelihood of an initiation using a probit regression, where the dependent variable equals 1 when an analyst initiates coverage.[16] We transform the fitted values from estimating this probit regression into a propensity score. The propensity score is the conditional probability of receiving an initiation in a given month conditional on the firm controls used in our initiation model. We pair firms with an initiation with two control firm observations using the nearest neighbor algorithm. Matching each initiation firm with two non-initiation firms provides added power for our tests, yielding a sample of 119,565 firm-months, corresponding to three observations for each of the 39,855 initiations.[17]

---

[16] We follow prior research in choosing variables associated with the probability of an initiation (see Liang et al. 2008). Our model of initiations includes firm size, prior analyst following, institutional ownership, trading volume, past returns, book-to-market, earnings variability, and indicators for events such as earnings announcements, management forecasts, and merger activity.

Columns (3) and (4) in Table 4 report the results from re-estimating Equation (3) using the propensity score matched sample. Column (3) results demonstrate that the coefficient on $INITIATION_{i,t}$ is positive and significant while the interaction term has a negative and significant coefficient. To mitigate concerns about heterogeneity that is not captured by our matching algorithm, column (4) includes the main controls used in our primary analyses.[18] We again find that the coefficient on $INITIATION_{i,t} * LNUM_{i,t-1}$ is significantly negative, while the coefficient on $INITIATION_{i,t}$ is significantly positive. These findings mirror those in Table 3, suggesting that new initiations contribute primarily to industry- and market-information while subsequent initiations contribute to firm-specific information. The consistency of our findings within the multivariate, propensity score matching approach mitigates concerns regarding selection based on observables and provides additional support for our main tests.

Trading Co-Movement and the Speed of Information Flow

Barberis et al. (2005, 284) point out that if investors place stocks into specific groups such as industries, and then allocate resources to these groups of stocks instead of individual assets, this process can generate co-movement. In the context of our study, initiations could introduce stocks to investors, causing them to group these stocks with other firms in their respective industries, thereby increasing synchronicity as the stocks trade together. We attempt to rule out this possibility by using synchronicity in *trading volume* to capture the shift in return synchronicity that is driven by the increased awareness of the stock but is unrelated to the information provided by the analyst.[19,20] We re-estimate Equations (3) and (4) after controlling for changes in volume synchronicity (untabulated) and find that the positive (negative) association between new (subsequent) initiations and the change in synchronicity is still present and of similar magnitude to the results presented in Table 3.

Analysts may also impact return synchronicity without affecting the mix of information available about a firm by simply speeding up the flow of information into prices. Implicitly, our methodology for measuring synchronicity assumes that market and industry price movements map into a firm's stock price on a daily basis, but a firm's price may actually take more than a day to synchronize with the market and industry (Barberis et al. 2005). To address this issue we calculate our synchronicity measure using two lags of the industry and market stock return and then re-estimate Equation (4). Our untabulated results show no change in the relation between initiations and changes in synchronicity. New (subsequent) initiations continue to be positively (negatively) related to changes in synchronicity with no significant decreases in the magnitude of coefficients in Table 3.

---

[17] Matching to only one other observation yields similar results.

[18] As discussed in Armstrong et al. (2010), the most common way to assess the reasonableness of the propensity score approach is to examine the covariate balance between the treatment group (firms with initiations) and control group (firms without initiations). Covariate balance is not achieved in our case, but this is common in practice (see Ho et al. 2007) and the recommended approach is to estimate a regression of the outcome (change in synchronicity) as a function of the treatment and the control variables used in the propensity score model.

[19] Subsequent initiations could also induce co-movement in trading, but given that our results document a decrease in synchronicity for these initiations and that investors should already be aware of firms with coverage, we believe this is less likely to be the case than for new initiations.

[20] To estimate trading volume synchronicity we regress shocks to daily share turnover, measured as shares traded scaled by shares outstanding, at the firm level on shocks to daily share turnover at the industry- and market-level. Because daily turnover is highly auto-correlated, we create shocks to our turnover measures by regressing daily turnover (at the firm-, industry-, and market-level) on six daily lagged values of turnover. The residuals from these regressions are then used in the volume analog of Equation (1) (Halling et al. 2011).

*, **, *** Indicate significance at the 0.1, 0.05, and 0.01 levels, respectively.

All variables are defined in Appendix A. t-statistics (in parentheses) are based on standard errors that are robust to heteroscedasticity and correlation across observations from the same two-digit SIC industry.

Alternative Measures of Information

Because synchronicity is not a perfect measure of the mix of information available about a specific firm, we use several alternative measures of the available information about a firm to assess the robustness of our main findings.

Analyst Forecast Errors

Earnings forecasts are an important channel through which analysts disseminate news and, thus, serve as an alternative measure of the type of information that analysts provide. In this section, we extend the analyses in Ayers and Freeman (1997) and Piotroski and Roulstone (2004) by examining the link between coverage initiations and the accuracy of analysts' forecasts. We conjecture that newly initiating analysts are more likely to incorporate industry-specific news than firm-specific news into their earnings forecasts and that the opposite holds for subsequent analysts. Thus, using earnings innovations as a proxy for news, we predict that the relation between industry-specific earnings innovations and consensus forecast errors is weaker following new initiations, while the relation between firm-specific earnings innovations and consensus forecast errors is weaker following subsequent initiations.

To investigate the relation between initiations and forecast errors, we measure seasonally adjusted earnings innovations, $\Delta E_{i,q}$, for each firm i and quarter q, where we scale innovations by the beginning of quarter price, $\Delta E_{i,q} = \frac{E_{i,q}-E_{i,q-4}}{P_{i,q}}$, where $E_{i.q}$ equals firm i's earnings per share for fiscal quarter q and $P_{i,q}$ denotes the beginning of quarter price. We next decompose $\Delta E_{i,q}$ into industry- and firm-specific components following Ayers and Freeman (1997). Specifically, we define the industry component of the current earnings innovation as the median earnings innovation of all firms in the same two-digit SIC code as firm i, denoted by $\Delta I_{i,q}$, minus the market earnings innovation, defined as the median value of $\Delta I_{i,q}$ for all industries in quarter q. Finally, we calculate the firm-specific earnings innovation, $\Delta F_{i,q}$, by subtracting $\Delta I_{i,q}$ from the total earnings innovation, $\Delta E_{i,q}$.

For each firm-quarter, we also calculate the consensus analyst forecast error, $FE_{i,q}$, defined as firm i's actual earnings minus the consensus forecast immediately prior to the quarterly earnings announcement, scaled by beginning-of-quarter price. Positive (negative) values of $FE_{i,q}$ correspond to cases where analysts are pessimistic (optimistic) relative to actual earnings. To complement our synchronicity-based tests, we examine the relation between the consensus analyst forecast error, $FE_{i,q}$, and the industry and firm-specific components of the earnings innovation.

We predict that new initiations increase the extent to which industry earnings news is reflected in consensus forecasts, while subsequent initiations increase the extent to which firm-specific earnings news is reflected in consensus forecasts. To test these predictions, we estimate the following regression:

$$\begin{aligned} FE_{i,q} = {} & \alpha_0 + \beta_1 \Delta F_{i,q} + \beta_2 \Delta F_{i,q} * INITIATION\_NEW_{i,q} + \beta_3 \Delta F_{i,q} * INITIATION\_SUB_{i,q} \\ & + \beta_4 \Delta I_{i,q} + \beta_5 \Delta I_{i,q} * INITIATION\_NEW_{i,q} + \beta_6 \Delta I_{i,q} * INITIATION\_SUB_{i,q} \\ & + \beta_7 INITIATION\_NEW_{i,q} + \beta_8 INITIATION\_SUB_{i,q} + \beta_9 LMVE_{i,q} + \beta_{10} LBM_{i,q} + \varepsilon_{i,q}, \end{aligned} \tag{5}$$

where $INITIATION\_NEW_{i,q}$ is a dummy variable that equals 1 when the firm experiences a new initiation in the 60 trading days prior to firm i's quarter q earnings announcement and we define $INITIATION\_SUB_{i,q}$ analogously for subsequent initiations.[21] If newly initiating analysts primarily provide market- and industry-information, then we expect to observe a negative coefficient on the interaction between $\Delta I_{i,q}$ and $INITIATION\_NEW_{i,q}$, consistent with new analysts reducing consensus forecast errors by incorporating the effects of industry earnings innovations into their forecasts. Similarly, if subsequent analysts primarily provide firm-specific information, then we expect to observe a negative coefficient on the interaction between $\Delta F_{i,q}$ and $INITIATION\_SUB_{i,q}$, consistent with subsequent analysts reducing consensus forecast errors by incorporating the effects of firm-specific earnings innovations into their forecasts.

---

[21] When $INITIATION\_NEW_{i,q}$ equals 1, the consensus forecast will generally consist of only the forecast from the initiating analyst, although there can be additional forecasts if there are subsequent initiations following the new initiation. In untabulated results, we find qualitatively identical results when $INITIATION\_NEW_{i,q}$ equals 1 and the new initiation is the only forecast or the consensus forecast consists of the new initiation and one or more subsequent initiations.

Analyst forecast errors and earnings innovations are obtained from I/B/E/S and Compustat, respectively. We eliminate firms whose stock price is less than five dollars to avoid scaling issues when measuring analyst forecast errors. The final sample consists of 116,699 firm-quarters spanning 1996–2007. All non-binary variables are standardized at the quarterly level to have a mean of 0 and a standard deviation of 1.

Table 5 presents the results from estimating Equation (5). The results demonstrate that analyst forecast errors are positively related to both contemporaneous innovations in industry and firm-specific earnings innovations, $\Delta I_{i,q}$ and $\Delta F_{i,q}$, respectively. All else equal, greater increases (decreases) in firm or industry-level earnings lead to analysts being overly pessimistic (optimistic) relative to realized earnings. In addition, the negative interaction term between $\Delta F_{i,q}$ and $INITIATION\_SUB_{i,q}$ demonstrates that subsequent initiations attenuate the relation between firm-specific earnings innovations and analyst forecast errors. All else equal, when an analyst initiates coverage on a firm already followed by other analysts, firm-specific earnings news is more likely to be reflected in the consensus forecast. In contrast, the interaction term between $\Delta F_{i,q}$ and $INITIATION\_NEW_{i,q}$ is positive but insignificant. These findings suggest that while subsequent initiations contribute to the incorporation of firm-specific earnings innovations into earnings forecasts, the same is not true of new initiations. The results also demonstrate a negative interaction effect between industry earnings innovations, $\Delta I_{i,q}$, and $INITIATION\_NEW_{i,q}$. The fact that we find a negative and significant interaction effect between industry earnings innovations and $INITIATION\_NEW_{i,q}$, while finding a positive and insignificant interaction effect between firm-specific earnings news and $INITIATION\_NEW_{i,q}$, is consistent with analysts primarily providing industry-earnings news when initiating coverage on firms without existing coverage.

We further document a negative interaction effect between industry earnings innovations and $INITIATION\_SUB_{i,q}$, consistent with subsequent initiations also contributing to the incorporation of industry-specific news into earnings forecasts. An F-test rejects the equality of the $INITIATION\_SUB_{i,q}$ interaction terms, consistent with subsequent initiations playing a larger role in the assimilation of firm-specific earnings news into the consensus forecast relative to the assimilation of industry-specific earnings news. Column (4) of Table 5 demonstrates that these relations are robust to including interaction effects between the components of the earnings innovations and firm size and book-to-market.

Taken together, the results of this section corroborate and extend the main analyses. The results provide additional evidence that the type of information provided by analysts varies depending on the existing level of coverage. Specifically, we show that new initiations are more likely to incorporate industry-earnings innovations into the consensus forecast, while subsequent initiations are more likely to incorporate firm-specific earnings innovations into the consensus forecast. Additionally, by documenting how the type of coverage initiation affects the type of information reflected in analysts' forecasts, the results highlight one of the potential mechanisms through which analysts affect the mix of industry- versus firm-specific information reflected in security prices.

TABLE 5

Estimation of the Relation between Analyst Forecast Errors, Firm and Industry Earnings, and Analyst Initiation

All variables are defined in Appendix A. t-statistics (in parentheses) are based on standard errors that are robust to heteroscedasticity and correlation across observations from the same two-digit SIC industry.

Other Measures of Information

In addition to examining analyst forecast errors, we use the market and industry betas from variations of Equation (1) and return kurtosis, measured over the same time period as return synchronicity, to assess how initiations affect the information available about a firm.

Market and industry betas should capture how a firm's returns move with changes in the market and industry returns. We regress firm returns on market returns ($MKT\_BETA_{i,t}$) and firm returns on industry returns ($IND\_BETA_{i,t}$) to obtain the betas and then replace changes in synchronicity around initiations with changes in these betas around initiations. Table 6 contains the results of estimating Equation (4) where the dependent variable equals the change in betas. The estimated coefficients on $INITIATION\_NEW_{i,t}$ ($INITIATION\_SUB_{i,t}$) are positive (negative) and significant when $\Delta MKT\_BETA_{i,t}$ or $\Delta IND\_BETA_{i,t}$ is the dependent variable.[22] These results are consistent with our primary findings.[23]

Roll (1988) documents that the kurtosis of the return distribution declines significantly when he eliminates daily observations associated with firm-specific news, suggesting that a change in kurtosis may be one way to measure the presence of firm-specific information. Accordingly, we replace the change in synchronicity with the change in kurtosis and re-estimate Equation (4). The results, presented in Table 7, show that subsequent initiations lead to an increase in kurtosis while new initiations have no appreciable effect on kurtosis. Decreases in coverage result in a decrease in kurtosis. Interpreting these results in the light of Roll (1988) suggests that subsequent initiations increase the amount of firm-specific information being impounded in price, while decreases in coverage have the opposite effect.

Other Robustness Checks

We now summarize several other untabulated robustness checks that do not alter the main inferences of our study. First, because analysts may simply choose to cover firms that receive more press coverage, and because press coverage may actually increase the amount of firm-specific news available (instead of analysts increasing a firm's exposure to the press), we include the change in media coverage as a control variable.[24] Second, we replace adjusted R^2 values in the calculation of synchronicity with raw R^2 values to ensure that our modifications to the adjusted R^2 measure do not affect our results. Third, we include fixed effects defined by industry and month instead of firm fixed effects. Fourth, we include a time trend in the regressions. Fifth, we use the Prais-Winsten procedure to correct for autocorrelation in the regression error terms reported in Table 3. Finally, we

---

[22] For completeness we also include $DROP_{i,t}$ and $DROP\_ZERO_{i,t}$ in the regressions. We document that when there is a drop in coverage in a given month the market and industry betas increase, which is consistent with the decrease in betas when there is a subsequent initiation. In untabulated results, we also include our volume synchronicity measure as a control variable. The coefficient on $INITIATION\_NEW_{i,t}$ ($INITIATION\_SUB_{i,t}$) remains positive (negative) and significant.

[23] Note that betas and R^2s can change independently of each other. They are only directly related under strict distributional assumptions regarding the variances of the dependent and independent variables. Given this, we have estimated the relation between changes in synchronicity and initiations while controlling for changes in betas. Results (untabulated) indicate that new (subsequent) initiations continue to have a positive (negative) relation with the change in synchronicity. Given that the R^2 of a regression is determined by the regression betas, the variance and covariance of the independent variables, and the variance of the idiosyncratic portion of the dependent variable, and assuming that initiations do not affect the variance and covariance of market and industry returns, our findings suggest that initiations affect a firm's stock return synchronicity through changes in the weight placed on market and industry returns (i.e., changes in betas) as well as changes in the idiosyncratic portion of the firm's returns.

[24] Eugene Soltes of Harvard Business School graciously provided data on media coverage (Soltes 2010).

include the fourth lag of the level of synchronicity in our regressions as firms with higher levels of synchronicity may experience higher or lower shifts in synchronicity.

VI. CONCLUSION

In this study, we examine how analyst initiations affect synchronicity in order to determine whether analysts provide market- and industry- or firm-specific information about the firms they cover. We show that initiations increase synchronicity among firms with no existing analyst coverage and interpret this result as evidence that the first analyst report for a firm predominantly provides industry and market information. In contrast, we find that coverage initiations of firms with existing coverage appear to decrease synchronicity. Thus, if other analysts are following the firm, then analysts who initiate coverage appear to provide firm-specific information. Our results contribute to the literature by suggesting that the information analysts provide relies critically on the presence of other analysts. Furthermore, we extend prior studies that examine the relation between returns and analyst initiations by also showing that initiations are important information events.

We solidify our findings by documenting that they are robust to alternative measures of the mix of information available about a firm. For example, we disaggregate earnings news into industry- and firm-specific components and examine each component's relation with consensus forecast errors. Consistent with our synchronicity-based tests, we show that new initiations reduce the sensitivity of consensus forecast errors to industry earnings innovations, while subsequent initiations are more likely to mitigate the relation between consensus forecast errors and firm-specific earnings innovations. These findings document how the type of coverage initiation affects the type of information reflected in analysts' forecasts, thus highlighting a potential channel through which analysts affect the mix of industry- versus firm-specific information reflected in security prices. We also show that our results are robust to efforts to control for the endogenous nature of coverage decisions.

While our results are important for understanding the type of information that analysts produce, we do not take a comprehensive approach to identifying the mechanisms through which analysts communicate this information to investors. For example, in addition to their earnings forecasts, do analysts convey specific components of earnings news through their written assessment of market and industry conditions and the firm's operations? Additionally, do investors learn about industry and market information by observing analysts' coverage decisions? We leave these questions to future research.

Synchronicity Variables		
R^2	=	coefficient of determination from the firm-month estimation of the model: $RET_{i,t} = \alpha + \beta_1 MKRET_{i,t} + \beta_2 INDRET_{i,t} + \varepsilon_{i,t}$, where *MKRET* is the value-weighted market return and *INDRET* is the two-digit SIC industry value-weighted return for day t (not including the return of firm i). The model is estimated using daily returns from the past three months for each firm-month with a minimum of 50 daily observations;
$SYNCH_{i,t}$	=	logarithmic transformation of R^2, defined as log $(R^2/(1-R^2))$;
$\Delta SYNCH_{i,t}$	=	change in synchronicity defined as $SYNCH_{i,t+3} - SYNCH_{i,t-1}$;
$MKT\_BETA_{i,t-1}$	=	β_1 from the firm-month estimation of the model: $RET_{i,t} = \alpha + \beta_1 MKRET_{i,t} + \varepsilon_{i,t}$, where *MKRET* is the value-weighted market return. The model is estimated using daily returns from the past three months for each firm-month with a minimum of 50 daily observations;
$\Delta MKT\_BETA_{i,t}$	=	change in the market beta defined as $MKT\_BETA_{i,t+3} - MKT\_BETA_{i,t-1}$;
$IND\_BETA_{i,t-1}$	=	β_1 from the firm-month estimation of the model: $RET_{i,t} = \alpha + \beta_1 INDRET_{i,t} + \varepsilon_{i,t}$, where *INDRET* is the two-digit SIC industry value-weighted return for day t (not including the return of firm i). The model is estimated using daily returns from the past three months for each firm-month with a minimum of 50 daily observations;
$\Delta IND\_BETA_{i,t}$	=	change in the industry beta defined as $IND\_BETA_{i,t+3} - IND\_BETA_{i,t-1}$;
$KURTOSIS_{i,t-1}$	=	average of three monthly values of kurtosis based on a firm's daily returns, i.e., this is the average of kurtosis measured in months $t-1$, $t-2$, and $t-3$; and
$\Delta KURTOSIS_{i,t}$	=	change in kurtosis defined as $KURTOSIS_{i,t+3} - KURTOSIS_{i,t-1}$.
Analyst Coverage Variables		
$INITIATION_{i,t}$	=	indicator variable set to 1 if an analyst initiates coverage on a stock in month t, 0 otherwise;
$INITIATION\_NEW_{i,t}$	=	indicator variable set to 1 if an analyst initiates coverage on a stock with no existing coverage in month t, 0 otherwise;
$INITIATION\_SUB_{i,t}$	=	indicator variable set to 1 if an analyst initiates coverage on a stock with prior coverage in month t, 0 otherwise;
$DROP_{i,t}$	=	indicator variable set to 1 if the level of analyst coverage declines from month $t-1$ to t;
$DROP\_ZERO_{i,t}$	=	indicator variable set to 1 if analyst coverage in month t is 0 and non-0 in month $t-1$;
$EXOG_{i,q}$	=	indicator variable set to 1 if there is an exogenous reduction in coverage in quarter q;
$NUM_{i,t-1}$	=	number of analysts covering firm i in month $t-1$; and
$LNUM_{i,t-1}$	=	natural log of 1 plus the number of analysts covering firm i in month t.
Other Variables		
$LMVE_{i,t}$	=	natural log of market value of equity (in millions) in month t calculated as price times the number of shares outstanding;
$\Delta LMVE_{i,t}$	=	change in the natural log of *MVE* defined as $LMVE_{t+1} - LMVE_{t-1}$;
$INST_{i,t}$	=	number of shares in firm i held by institutions in month t divided by the total number of shares outstanding. We obtain data on institutional holdings from the CDA/Spectrum database;

(continued on next page)

APPENDIX A (continued)

Variable		Definition
$\Delta INST_{i,t}$	=	average value of $INST_{i,t}$ in months $t+1$ to $t+6$ less the average value of $INST_{i,t}$ in months $t-1$ to $t-6$;
$VOL_{i,t-1}$	=	log of the average trading volume in the six months prior to month t, $VOL_{i,t-1}$;
$TURN_{i,t}$	=	number of shares traded in month t divided by total shares outstanding;
$\Delta TURN_{i,t}$	=	average value of $VOLUME_{i,t}$ in months $t+1$ to $t+6$ less the average value of $VOLUME_{i,t}$ in months $t-1$ to $t-6$ scaled by the total number of shares outstanding in month t;
$RET\_12_{i,t}$	=	market-adjusted return on the firm's stock from $t-12$ to $t-1$;
$ISSUE\_12_{i,t}$	=	indicator variable set equal to 1 if the firm issued equity in the past 12 months, 0 otherwise;
$REPORT_{i,t-1}$	=	indicator variable set equal to 1 if the firm reported earnings in month $t-1$, 0 otherwise;
$GUIDE\_6_{i,t}$	=	indicator variable set equal to 1 if the firm issued earnings guidance within the last six months, 0 otherwise;
$BM_{i,t-1}$	=	book-to-market ratio in month $t-1$ defined as book value divided by MVE;
$LBM_{i,t-1}$	=	natural log of the book-to-market ratio in month $t-1$ defined as book value divided by MVE;
REG_i	=	indicator variable set equal to 1 if the firm belongs to a regulated industry, namely financial services or utilities;
$STDROA_{i,t}$	=	standard deviation of return on assets (ROA) measured over current and previous four quarters;
$\Delta E_{i,q}$	=	seasonally adjusted earnings innovation, scaled by price: $\Delta E_{i,q} = \frac{E_{i,q} - E_{i,q-4}}{P_{i,q}}$, where $E_{i,q}$ equals firm i's earnings per share for quarter q and $P_{i,q}$ denotes the beginning of quarter price;
$\Delta I_{i,q}$	=	industry component of the current earnings innovation defined as $\Delta IE_{i,q} - \Delta ME_{i,q}$, where $\Delta IE_{i,q}$ is the median earnings innovation of all firms in the same two-digit SIC code as firm i and $\Delta ME_{i,q}$ is the median value of $\Delta IE_{i,q}$ for all industries in quarter q;
$\Delta F_{i,q}$	=	firm-specific earnings innovation, $\Delta F_{i,q}$ defined as $\Delta E_{i,q} - \Delta IE_{i,q}$; and
$FE_{i,q}$	=	consensus forecast error defined as firm i's actual quarter q earnings minus the consensus forecast immediately prior to the quarterly earnings announcement, scaled by beginning of quarter price.

ABSTRACT: This study addresses the two-way process in which a subordinate and a superior engage in influence activities (bottom-up) and favoritism (top-down) in subjective Performance Evaluation. The research context is the Chinese government's evaluation of Chinese state-owned enterprises (SOEs) by the State-Owned Assets Supervision and Administration Commission of China (SASAC). We analyze archival records of the government's evaluation scores, score adjustments, and evaluation ratings given to 63 SOEs between 2005 and 2007. These analyses are also interpreted based on insights gained from in-depth field interviews with SASAC officials and chief financial officers (CFOs) of SOEs. Results indicate that the political connection of SOE CFOs, the geographic proximity of SOE headquarters to the SASAC central office, and political rank of the firm affect the SASAC's evaluations.

Keywords: *subjective Performance Evaluation; favoritism; influence activities; political connections; geographic proximity; State-Owned Asset Supervision and Administration Council (SASAC); Chinese State-Owned Enterprises (SOEs).*

Data Availability: *Data used in this study cannot be made public due to a confidentiality agreement.*

We greatly appreciate the helpful comments and suggestions from two reviewers, Rajani Krishnan (editor), John Harry Evans III (senior editor), Jasmijn Bol, Clara (Xiaoling) Chen, Lei Chen, Francisco de Asis Martinez-Jerez, Kelsey Dworkis, David Erkens, Chris Ittner, Charles Lee, Joan Luft, Neale O'Connor, Joe Piotroski, Claudia (Zhen) Qi, Tatiana Sandino, Wim Van der Stede, Feng Tian, and participants in the 2010 MAS Conference. We also gratefully acknowledge the research assistance of Jiaxiang Chen and Xi Yan.

I. INTRODUCTION

The purpose of Subjective Performance Evaluation (SPE) is to allow a superior to include information relevant to subordinate's work performance that is not incorporated in objective performance measures (Holmstrom 1979; Prendergast and Topel 1996). Studies by Gibbs et al. (2004) and Nisar (2007) suggest that including subjectivity in Performance Evaluation increases subordinate pay satisfaction, sales productivity, and trust between superiors and subordinates. While SPE allows a superior to include more information in subordinate Performance Evaluation, it also increases the likelihood of influence activities, since it provides more opportunities for subordinates to affect superior evaluation decisions and for superiors to make discretionary judgments by playing favorites (Gibbs et al. 2004).

Empirical studies in this area have emphasized the decision-influencing behavior of subordinates' activities, while focusing less on the role of favoritism on the part of the superiors.[1] This study empirically assesses the two-way relationship in a subjective Performance Evaluation process by determining how subordinates attempt to influence their evaluations and how superiors engage in favoritism with particular subordinates (Prendergast and Topel 1996).

Our research setting is the Chinese government's evaluations of 63 state-owned enterprises (SOEs—the subordinates) by the State-Owned Assets Supervision and Administration Commission of the State Council of China (SASAC—the superior). The study draws on the archival records of the Chinese government's evaluation scores, score adjustments, and evaluation ratings of 63 SOEs between 2005 and 2007, as well as in-depth field interviews with chief financial officers (CFOs) of 6 SOEs. We identify the factors that influence governmental evaluations of SOEs in addition to the financial performance indicators that the SASAC claims to use when evaluating SOEs. To address this research question, we use a database prepared by the SASAC that contains several levels of our dependent variables—the scores, ratings, the assignment of cutoff scores, and the *ex post* adjustments in scores/ratings.

Chinese SOEs play a critical role in the Chinese and world economies. At the end of 2007, the SASAC list of supervised firms contained 152 of the largest firms owned by the Chinese central government, whose asset size totaled 14.9 trillion RMB (US$2.1 trillion), and whose annual earnings totaled 1 trillion RMB (US$140 billion), accounting for 4 percent of China's annual gross domestic product (GDP). As of December 2007, 16 Chinese central government controlled SOEs were on the *Fortune* 500 list. By the end of 2011, this number has increased to 38. Each year the SASAC evaluates the performance of each central government controlled SOE in China, giving it a score based on three metrics: (1) the levels of budgetary targets on key financial indicators; (2) actual performance on the same set of key financial indicators; and (3) the degree of target difficulty as predetermined by the SASAC. Of relevance to our study is that the SASAC engages in *ex post* subjective adjustments of evaluation scores on a case-by-case basis. The SASAC makes personnel and compensation decisions based on these final evaluation scores and ratings.

Evidence from our field interviews illustrates the two-way process in which subordinates (using a bottom-up approach) and superiors (using a top-down approach) can affect subjective Performance Evaluation. From the SOE (subordinate) perspective, Performance Evaluation influences SOE executives' compensation and their political advancement, and executives are motivated to maximize performance on measures in the official evaluation formula. When subjectivity is included in the appraisal process, SOE executives have the opportunity to engage in influence activities with superiors by privately communicating information to the SASAC, engaging in joint social activities with SASAC officials, and attempting to manipulate the SASAC's perceptions of their performance in order to appear more competent (Milgrom and Roberts 1992). We assess the level of influence activities on the part of SOEs by looking at the effects of two factors on the SASAC's evaluations—the political connections of top executives of the SOEs and the geographic proximity between SOE headquarters and the central SASAC office. Further, we study how two other factors related to favoritism affect the SASAC's evaluation scores and ratings of SOEs—the SASAC's determination of whether an SOE is fulfilling strategic government objectives, and the political rank of an SOE.[2]

---

[1] Bol et al.'s (2010) study, while not directly related to ours, is the first empirical study to look at how superiors adjust sales targets to promote fairness.

Results suggest that both CFO connections, an executive identity variable that proxies for influence activities, and SOE political rank, a firm identity variable that proxies for government favoritism, affect evaluation scores, ratings, and *ex post* score adjustment. To better understand whether these factors influence how governmental discretion is used to apply favoritism, we further test their role in the target-setting process and cutoff scores assignment. Results indicate that highly ranked SOEs and SOEs that compete in strategic industries obtain fewer points in achieving targets based on common measures, and obtain more points in achieving targets based on firm-specific measures than less highly ranked SOEs or SOEs not in strategic industries. The government assigns cutoff scores to the benefit of high-ranked SOEs, which is consistent with the government playing favorites with a certain set of SOEs.

Our paper proceeds as follows. In Section II we present institutional details relating to the development of the SASAC and how it conducts Performance Evaluations of SOEs. In-depth field interviews conducted with SOE CFOs and high-ranking officials of the SASAC also informed this and the following section. Section III provides the theoretical framework motivating our investigation and presents our research hypotheses. In Section IV we test our hypotheses using archival data and present our results. Section V concludes the paper with a summary, discussion, and suggestions for future research.

II. INSTITUTIONAL BACKGROUND

The state-owned enterprise (SOE) system in China has undergone enormous changes in the last three decades. SOEs were initially part of the Chinese government, but reforms gave them increasing autonomy so that, by the early 1990s, many SOEs had become independent production and management entities. The State-Owned Assets Supervision and Administration Commission (SASAC) was created in November 2002, and charged with establishing a "new state asset management system in which authority, duty, and responsibilities are united, and in which management of assets, personnel, and affairs is unified" (SASAC 2006). The SASAC represents the scaling back of government authority through the creation of an arm's-length regulatory body, and is designed to be a powerful and authoritative board of directors. The roles of the SASAC include monitoring enterprise operations to protect the rights of the government owner; dispatching supervisors to audit and monitor the enterprise; appointing members of boards of directors and establishing procedures for appointing managers; approving major decisions in enterprise operations, including mergers, bankruptcies, and the issuance of new securities; and reporting on enterprise performance and revenues to the appropriate level of government. The SASAC also issues guidelines to direct strategic pathways for the SOEs.

To understand the evaluation timeline and procedures better, we conducted in-depth interviews with two high-ranking officials from the Performance Evaluation bureau of the SASAC and with

---

[2] In this research setting, the government evaluator (the SASAC) is the sole decision maker that decides which industries are strategic industries, and assigns political rank to these SOEs. An SOE is not able to influence its own industry or its political rank. These two measures allow us to disentangle governmental favoritism from influence activities.

CFOs of six central government controlled SOEs in July 2009. We use insights gained from these interviews to increase our knowledge of the institutional aspects of the paper and to clarify particular findings in the results section. The interviews included a broad range of companies in different industries, including equipment manufacturing, military supply, metallurgy, commercial trade, petroleum, and a large investment holding company. We conducted three interviews in person at companies in Beijing and three others via conference calls to companies headquartered outside Beijing. We conducted all interviews in Mandarin with two of the co-authors present. We followed a strict interview protocol asking the same set of open-ended questions in the same order across all six firms and obtained insights into whether SPE, SOE influence activities, or governmental favoritism exist in the Performance Evaluation of SOEs managed by the SASAC. More specifically, we were interested in how different aspects of SPE may have affected the SASAC's Performance Evaluation scores and ratings of SOEs, and the potential factors that may have led to more favorable governmental ratings. Each interview lasted approximately three hours. By the sixth interview we did not learn anything that was significantly different from previous interviews and, thus, terminated the interview process.

Five Stages of the SASAC's Performance Evaluation Process

In this section we describe the five stages that the SASAC goes through to determine an SOE's Performance Evaluation score.

Stage 1: Operational Target Setting

In the fourth quarter of each year, the SASAC begins a Performance Evaluation process for the following year by setting performance targets for SOEs. Target setting is a bottom-up process in which the SOEs propose annual operational targets, and the SASAC either approves or adjusts those targets. Setting an operational target that is either lower than last year's actual performance or lower than the average of the last three years precludes an SOE from getting a top rating in the next annual Performance Evaluation. At the end of March, after the SASAC and SOEs have reached consensus regarding targets, an SASAC representative signs a performance responsibility contract with the so-called "Persons in Charge" of each SOE.

Each SOE sets targets based on four measures as shown in Appendix A. The first two measures are mandatory: earnings before tax and extraordinary items (EBT), and return on equity (ROE). Each SOE must also choose two of the following three other measures: inventory turnover, accounts receivable turnover, or sales growth. Details of the scoring are discussed below.

Stage 2: Operational Results Verification

Before the end of April each year, CFOs of the SOEs prepare annual performance reports, which include a budget variance analysis and an operational performance summary based on audited annual financial statements for the previous year. These mandatory reports are submitted to the SASAC and its supervising committee. The SASAC verifies and evaluates each SOE's performance in relation to its annual operational targets. SOEs may voluntarily disclose additional information to the SASAC when they submit the performance reports. For example, if unfavorable variances occur, they can provide a detailed explanation for the variances.

Stage 3: Raw Score Calculation

The SASAC verifies the operational results of the SOEs and calculates their raw evaluation scores. The raw scores range from a minimum of 72 to a maximum of 120 points. The comprehensive score for each SOE's annual Performance Evaluation is the sum of the points awarded for target achievement on each measure, multiplied by the degree of operational difficulty given that an SOE meets all performance targets. When an SOE achieves a specific target measure, points earned on that measure are multiplied by the degree of difficulty parameter, a parameter > 1 for every SOE as shown in Appendix A.

The degree of operational difficulty is a subjectively determined parameter based on assets, revenue, total profit, return on equity, number of employees, and ratio of retired employees to total employees. This parameter varies across years for different firms. The degree of operational difficulty parameter is assigned to each SOE after all SOE audited financial statements have been submitted to the SASAC. The SASAC then compiles a list that ranks all SOEs based on the current-year assets, revenue, total profit, return on equity, number of employees, and ratio of retired employees to total employees. Using this rank, the SASAC then subjectively assigns the degree of difficulty parameter to each SOE.[3]

Stage 4: **Ex Post** *Discretionary Adjustment*

After calculating the raw scores of all SOEs, the SASAC makes *ex post* discretionary adjustments to each SOE's score based on subjective criteria. The SASAC indicates that they deduct punishment points from raw scores if enterprises have severe safety incidents or have been involved in financial fraud or other scandals. Enterprises that have acquired financially distressed enterprises out of political concerns receive bonus points (SASAC 2008). The SASAC makes *ex post* discretionary adjustments to SOE Performance Evaluation scores on a case-by-case basis, and all such adjustments publicly available online.

Stage 5: Ratings Assignment

The Performance Evaluation Bureau prepares a comprehensive working document that includes all SOE fulfillment or non-fulfillment of targets, degrees of difficulty, raw scores, subjective adjustment scores, and final scores sorted from the highest to the lowest final score. Based on this document, SASAC directors determine cutoff scores with which to assign each SOE to one of five classes: A, B, C, D, and E. A score of "C" or above is considered acceptable and SOE executives in D- and E-ranked firms may be asked to step down from their current positions by SASAC officials.

SOE executives are motivated to influence the perceptions of government superiors and engage in private communication with government superiors because evaluation ratings affect their performance-based bonuses and their career advancement.[4]

The SASAC notifies the executive of each SOE of their confirmed evaluation scores and ratings. An executive can appeal the rating to the SASAC. The SASAC reports the Performance Evaluation results to the State Council of China, and makes bonus and personnel decisions based on Performance Evaluation results. Our field interviews suggest that firms care more about the ratings (A–E) than their scores *per se*. All of the CFOs and SASAC officials we interviewed agreed that

---

[3] We were unable to obtain further details regarding the specific formula used by the SASAC to calculate the degree of difficulty parameter of individual SOEs.

[4] Performance-based bonuses are influenced by evaluation rank in a piece-linear manner: SOE executives of A-ranked firms can get bonuses of 2 to 3 times their base salaries; SOE executives of B-ranked firms can get bonuses of 1.5 to 2 times their base salaries; SOE executives of C-ranked firms can get bonuses of 1 to 1.5 times their base salaries; SOE executives of D-ranked firms can get bonuses of 0 to 1 times their base salaries; and SOE executives of E-ranked firms get 0 bonuses. In addition, part of the bonuses of SOE executives of D- and E-ranked firms are deducted as punishment, depending on how large the gaps are between their evaluation scores and the minimum scores of C-ranked firms.

SOE executives carefully monitor the ratings assigned to them by the SASAC, in part because of economic concerns, but primarily because of issues of face and honor.

III. THEORETICAL FRAMEWORK

Subjective Performance Evaluation of State-Owned Enterprises (SOEs)

SOEs differ from their private counterparts because of their roles as business entities and agents of the government. As governmental agents, they are responsible for achieving multiple objectives, including creating jobs, promoting industrialization, advancing technologies, defending national security, and subsidizing underdeveloped areas of the country. Since the SOEs work toward multiple goals, the government uses multiple measures to evaluate both the economic efficiency and the social effectiveness of these SOEs. Some of these measures may be contradictory with one another and may be difficult to quantify. Subjective Performance Evaluation is a mechanism used by the Chinese government and individual politicians to focus SOEs on the goals and objectives important to the government and to individual politicians.

Influence Activities and Tactics Used by SOEs to Influence the SASAC

Influence activities occur when agents attempt to affect a superior's decisions for their own private benefit (Milgrom 1988; Milgrom and Roberts 1988, 1992; Meyer et al. 1992). In organizations where individuals have discretion over decisions that have distributional implications, influence activities inevitably arise (Inderst et al. 2005). Since subjective Performance Evaluation directly affects the compensation and promotion of SOE executives, they are motivated to engage in influence activities in the subjective evaluation process. While the SASAC centralizes authority over SOEs, CFOs have private information regarding their own performance, which exacerbates the potential for costly efforts to influence the SASAC evaluation decisions. The costs of engaging in influence activities include wasted subordinate effort and time, inefficient decision-making, and deadweight losses in firm value (Milgrom 1988; MacLeod 2003).

More specifically, influence activities include direct personal appeals, offers of reciprocity, and the use of rational persuasion and consultation (Ciadini 1984; Yukl et al. 1993). Higgins et al. (2003) suggest that these types of ingratiation activities have positive effects on work outcomes. SOE executives may attempt to manage perceptions regarding their own performance to make themselves look more competent in the eyes of supervisors. They may also be motivated to create a generally good impression with supervisors to gain higher evaluation scores (Milgrom and Roberts 1988). The CFOs we interviewed confirmed that SOEs are likely to actively communicate with the SASAC during the Performance Evaluation process. They suggested that such SOE initiated communication should include "an early start," "a timely follow-up," and "a creative mentality."

Our field interviews suggest that SOE executives frequently use two types of influence tactics when communicating with SASAC officials. The first tactic is persuasion, which is the use of logical arguments and factual evidence to persuade others that their proposals or special requests are viable, reasonable, and may aid long-term sustainable growth of their firms (Yukl et al. 1993). One commercial trade company successfully convinced the SASAC to adjust their operational targets during the evaluation period. The company's CFO believed that the persuasion strategy was very effective:

> A 2 percent Renminbi appreciation can immediately cause exchange losses of 40 million U.S. dollars in our company. By no means could we foresee our central government reforming the Renminbi exchange rate system on July 21, 2005. (We were) considering which would be the most effective way to communicate with the SASAC about our difficult situation and to ask them for special treatment. We decided to hold a seminar; we

> invited all commercial trade companies in Beijing to discuss how Renminbi appreciation would influence exchange losses in 2005, and of course, we invited officials from the SASAC to attend our seminar. Using this strategy, we were able to convey our message clearly to the SASAC and successfully convince them to upwardly adjust our profit number by 31 million U.S. dollars in that evaluation period.

The second tactic used by SOEs is consultation. The SOEs proactively consult with SASAC officials and solicit the participation of the SASAC in planning strategy, activity, or change, showing the SASAC their willingness to modify a proposal in response to concerns and suggestions. One CFO remarked:

> It would be way too late if we waited until operational results are submitted to the SASAC to start communicating with the SASAC. We have to strategically set targets to better fulfill our promise to the SASAC as specified in our performance responsibility contract.

Another CFO explained:

> We call SASAC officials who are assigned to calculate the score for our firm once a week during the evaluation period.

Political Connections, Geographic Proximity, and SOE Influence Activities

According to social identity theory (Tajfel and Turner 1986), people are attracted to those who belong to the same social categories (an in-group identity), and this attraction has real economic consequences. For example, research on Performance Evaluation has found that older employees are rated lower on task performance and citizenship behavior by younger supervisors than by older supervisors (Tsui and Egan 1994). People have multiple sources of identity, and those sources vary in their salience depending on the social context.

In our setting, one likely social identity category is the political connections of executives in the SOEs to those members of the SASAC. SOE executives with a prior career history in the government are more familiar with the bureaucratic systems, administrative procedures, and macro-perspectives taken by government officials when making decisions. SOE executives with previous government experience often share similar ideologies and aspirations with SASAC officials, understand the inner workings of the bureaucracies, and can better use the language of the Chinese Communist Party when communicating with SASAC officials. As noted by an SASAC official:

> Former governmental officials think like governmental officials even after joining boards of directors of big SOEs. They tend to approach questions from a macro-economic perspective, and from the industry-wide perspective. They understand to what extent the government wants to regulate the industry and why. This is a unique difference between politically connected SOE executives and internally promoted executives in SOEs.

Another CFO explained:

> The experience of serving as governmental officials facilitates communication of SOE executives with SASAC officials.

Politically connected executives share a higher level of in-group identity with SASAC officials than do less-connected executives. A shared group identity facilitates the influence tactics of persuasion and consultation. In addition, levels of trust and reciprocity are higher and friendships and a sense of loyalty are stronger among in-group members. All of these factors can facilitate successful influence activities.

This discussion is summarized in our first hypothesis:

> **H1 (The Political Connection Hypothesis):** SOEs with executives having stronger political connections with the Chinese government receive more favorable evaluation scores from the SASAC than do SOEs whose executives have weaker political connections with the Chinese government.

Another social identity category is the geographic proximity between superiors and subordinates. Geographic proximity implies common dialects (Farh et al. 1998) and similar alumni networks (Faccio 2006), both of which facilitate social relations among people. More frequent business and social interactions between officials and business executives through leisure and social activities are likely to provide more favorable views of each other and easier communication. A study by Landier et al. (2009) of more than 250 firms with approximately five divisions within each firm showed that business divisions that were closer to headquarters were less likely to face layoffs and to be divested. SASAC officials may feel a higher level of social pressure for giving a low rating to a geographically proximate SOE, since they are more likely to know local individuals, be members of the same regional business community, and observe more directly how an individuals' personal welfare is affected.

Geographic proximity, or "home bias" as coined by Covrig et al. (2007), also implies lower communication costs and information advantages (Schultz 2003), which may influence a variety of economic behaviors. These include holding a higher proportion of local stocks in investment portfolios (Grinblatt and Keloharju 2001), higher returns of fund investors on their investments in local firms (Coval and Moskowitz 2001), more accurate forecasts by analysts about firms in closer proximity to their own brokerage firms (Malloy 2005), and higher acquirer returns for acquisitions within closer geographic proximity (Uysal et al. 2008). Incurring higher information-gathering costs can cause supervisors to be less willing to invest the required time in information collection and it is possible that SOEs with headquarters located closer to the central SASAC office in Beijing will have a greater likelihood of receiving a more accurate adjustment from the SASAC central office. Our interviews indicated how geographic proximity helps communication between SOE executives and SASAC officials. As one CFO observed:

> SOEs located in Beijing enjoy great information sharing and knowledge exchange with SASAC officials. First of all, the SASAC invites CEOs of excellent-performing SOEs to come visit their central office in Beijing and give lectures on various management topics such as Economic Value Added (EVAs), budgetary management, continuous improvements, or balance scorecards. We always attend these lectures.

Another CFO put it this way:

> The most frequent communication between the SASAC and us does not take the form of letters, emails, or telephone calls. We believe walk-in visits show more commitment, and we always bring supporting documentation that explains our operational situation in detail when visiting the SASAC office.

This discussion leads to our second hypothesis:

> **H2 (The Geographic Proximity Hypothesis):** SOEs with headquarters located closer to the SASAC central office receive more favorable evaluation scores from the SASAC than SOEs with headquarters located farther from the SASAC central office.

SPE and Governmental Favoritism

Favoritism occurs when superiors, acting on personal preferences, show partiality to some subordinates over others (Prendergast and Topel 1996). Subjectivity in Performance Evaluation facilitates favoritism because it provides superiors with the discretion to adjust performance ratings based on subjective factors that they observe. Like all Performance Evaluation processes, favoritism can have both positive and negative consequences depending on the superior's motivations. Some superiors may use their power to adjust evaluations based on having better information, but others may simply use their power for personal gain or satisfaction. Favoritism can be demoralizing to subordinates if the perception of credibility and fairness of the Performance Evaluation system is diminished. One way of reducing the possibility of favoritism is to install a system of accountability such that higher-level executives review all Performance Evaluations. This solution does not appear to be viable in our research setting. Officials in the Performance Evaluation Bureau of the SASAC are government bureaucrats for whom seniority plays a key role in compensation and promotion decisions, and these officials are not motivated to invest effort to gather information to make accurate subjective evaluations. Thus, we expect subjectivity to lead to favoritism in the annual Performance Evaluation of SOEs.

Our interviews suggest that SASAC officials want SOEs to perform well, to fulfill social goals, and to perform in a manner that can advance the official's own career. Thus, we expect the government to favorably rate those SOEs that assume more social responsibility than those that do not, a preference that can be revealed in analyzing subjective Performance Evaluation scores assigned by the SASAC. For example, the SASAC may favorably rate those who compete in strategic industries such as the military and petroleum industries and those companies that provide more employment opportunities. Consistent with the social responsibility argument, is this statement from a CEO:

> We believe getting A ratings bolsters employee morale, and distinguishes our firm from average performers. We contribute greatly to our nation's basic industries; we provide a tremendous amount of jobs, especially in minority areas. We deserve to get A's no matter how the SASAC weights economic profits versus social benefits.

A CFO from another large SOE told us that:

> There are 460,000 employees in our firm. We have taken such and such steps in creating job opportunities, and have contributed greatly to the central government's call to reduce unemployment. Of course, the SASAC should favor us and reward us for taking on social responsibility in addition to creating economic value.

These observations lead us to our third hypothesis:

> **H3 (The Social Responsibility Hypothesis):** SOEs that assume more social responsibilities receive more favorable evaluation scores from the SASAC than SOEs that assume fewer social responsibilities.

Politicians act out of self-interest and are likely to intervene in firm activities to fulfill their personal agendas. Typically, politicians need money, information, and votes to advance their careers. To advance their careers, politicians would treat firms with more assets that can afford larger campaign contributions, firms with more employees that provide a larger constituency, and firms located in political centers with politically influential CEOs, that provide richer information content and broader information channels, more favorably. We expect government officials to favorably rate SOEs that are willing to return the favor by helping to advance these officials' careers.[5] SOEs with higher political rank are likely to have more strategic allies and partners in critical political circles than SOEs of lower political rank. As a result, we speculate that the SASAC officials in charge of subjective evaluations will be more likely to evaluate those SOEs with higher political rank more favorably. One CFO noted:

---

[5] In China, officials are selected through a top-down process initiated every five years by the Organization Department of the CPC Central Committee. Central government officials are elected, followed by elections of provincial, city, county, and township officials. In this process, catering to the desires of high-ranking politicians may be just as important as fulfilling the will of the populace.

> SASAC officials value networking with SOE managers, especially with those CEOs who have potential to be promoted to provincial directors. For example, Mr. W, the former CEO of CNOOC has now been promoted to secretary of the Hainan Provincial Committee of the Communist Party of China (CPC) Committee.

An SASAC official noted that the SASAC is "unfair" when setting cutoff scores and that the SASAC shows favoritism, especially to firms with higher political rank:

> Let's say that the Performance Evaluation bureau finishes summarizing all final performance scores ranked in order from highest to lowest. The director's office decides that 20 percent of the SOEs can be rated as A-level firms. By mechanical calculation, we know that the critical value should be 132. However, if a vice-ministerial-level petroleum firm gets a score of 131.5, chances are that the SASAC will finally lower the cutoff score to 131 to make room for the petroleum firm on the A-list.

This discussion leads to our fourth hypothesis:

> **H4 (The Political Rank Hypothesis):** SOEs with higher political rank receive more favorable evaluation scores from the SASAC than SOEs with lower political rank.

IV. SAMPLE, ANALYSES, AND RESULTS

Data

The data we use in our tests are derived from the following data sources: (1) a proprietary database of annual Performance Evaluation results assigned to central government controlled SOEs prepared by the SASAC from 2005 to 2007; (2) audited financial reports of 63 SOEs from the initial issuance statements of firm bonds from 2005 to 2007; and (3) complete personnel records of the top management teams of 63 SOEs from the initial issuance of firm bonds or from rating agency reports from 2005 to 2007. We obtained the remaining resumes from websites of individual companies. Our final sample consists of 63 state-owned enterprises and 189 firm-year observations.

Measurement of Variables

SOE Executives' Political Connections

Political connections considered in our study derive from career histories of SOE executives as officials in the Chinese government. The first measure of CEO political connections is *CEOConnection*, which is based on scores assigned to the highest bureaucratic positions held by CEOs before they joined the top management teams of their SOEs. We assign the highest level of political connections to those executives who have held top positions in the central government, followed by individuals in the provincial and the municipal governments. The corresponding *CFOConnection* measure is coded in the same way.[6]

---

[6] We improve on previous measures of political connections that treated political connections as a dichotomous variable. We manually collected detailed resume data of top management team members of Chinese SOEs, and coded the political connection measures as the sum of the score on an individual's highest career title earned in his or her previous political career before joining the boards of directors of SOEs and the score on the individual's highest-ranking government position.

Geographic Proximity from SOE Headquarters to the SASAC Central Office

We measured geographic proximities using *Distance*,[7] the log transformation of the exact physical distance between headquarters of SOEs and the SASAC central office. This is consistent with Landier et al.'s (2009) approach that calculates the log transformation of spherical distance as the number of miles between the longitude and latitude of two different locations.

Social Responsibility of SOEs

Social responsibility is proxied by two measures. The first measure is the log transformation of employees (*Employees*) scaled by the total assets of each SOE. This number includes retired employees. The second measure reflects the industry in which individual SOE competes (*StrategicIndustry*). *StrategicIndustry* is coded as 1 in those industries in which the Chinese government seeks to retain greater power, including the military, electric power, petroleum and petrochemical, telecom, coal, civil aviation, and shipping and transportation industries. Panel B of Table 1 shows the distribution of industries in which SOEs compete in our sample. Twenty-seven SOEs are categorized into strategic industry groups and 36 SOEs are categorized into non-strategic industry groups, according to the industry classification standard prepared by the SASAC.

Political Rank of SOEs

Political rank (*SOEPoliticalRank*) means the "bureaucratic rank"[8] of the firm. We use two criteria to code the political rank of individual SOEs: whether a SOE is a "vice-ministerial level" firm[9] or whether the CEO of the SOE is assigned by the Organization Department of the CPC Central Committee. Political rank is coded as 2 for the largest 13 "vice-ministry level" firms whose CEOs are appointed by the Organization Department of the CPC Central Committee. Political rank is coded as 1 for the next tier of 40 firms whose CEOs are appointed by the Organization Department of the CPC Central Committee. Political rank of all other central government controlled SOEs is coded as 0, and the CEOs of these SOEs are appointed by the SASAC, which reports to the State Council and the CPC Central Committee.

Control Variables

Earnings before tax and extraordinary items (*EBT*), return on equity (*ROE*), the inventory turnover rate (*INTurnover*), the accounts receivable turnover rate (*ARTurnover*), and sales growth (*SalesGrowth*) serve as control variables as all SOEs are evaluated based on these measures, and the raw evaluation score of each SOE is the sum of the points granted for achieving targets based on these measures.

We use the degree of operational difficulty (*DegreeofDifficulty*) as a control variable in our empirical tests. The SASAC subjectively assigns to each SOE a parameter called the degree of operational difficulty based on assets, revenue, total profit, return on equity, number of employees, and ratio of retired employees to total employees. The comprehensive score of each SOE is a raw evaluation score multiplied by the degree of operational difficulty parameter.

---

[7] As a robustness check, we use a dummy indicator, *Local*, that takes the value of 1 if the headquarters of a SOE is located in Beijing, where the central SASAC office is located. Results remain the same.

[8] SOEs have political rank for two reasons. First, before the reform separating state-owned enterprises from the government, all SOEs used the same coding system of political rank as the one used by the Chinese government. Chinese SOEs would follow the wording of government administrative rank with "section chief," "head of the department," or "head of the bureau," to distinguish the administrative rank of firm employees. Second, some SOEs were directly converted from governmental ministries during reforms that streamlined and merged governmental ministries.

[9] "Vice-ministry level" central government controlled SOEs means that their CEOs have the same political rank as vice-ministers of central government ministries.

We use organizational size as an additional control variable since our field observations suggest that size may be related to higher evaluation scores and ratings.[10] Variable measurements are described in Appendix B.

Summary Statistics

Panel A of Figure 1 shows the population distribution of SASAC evaluation scores for all 152 central government owned SOEs from 2005 to 2007. Among all 152 SOEs, we were able to extract the personnel information and complete financial indicators of 63 SOEs, whose distribution of SASAC evaluation scores is reported in Panel B of Figure 1. Panel C of Figure 1 shows the cutoff scores in the SASAC ratings assignment. Panel D of Figure 1 shows the number of SOEs that were in each class from 2005 to 2007 for the population of all 152 central government controlled SOEs. As shown in Panel D of Figure 1, the percentage of SOEs obtaining a Performance Evaluation of A increased from 18.1 percent in 2005, to 26.3 percent in 2007. The percentage of SOEs obtaining a Performance Evaluation of C decreased from 26.3 percent in 2005, to 18.4 percent in 2007. The sample distribution in Panel E of Figure 1 is consistent with this data pattern, showing that the percentage of SOEs obtaining a Performance Evaluation of A increased from 28.6 percent in 2005 to 46.0 percent in 2007, and that the percentage of SOE obtaining a Performance Evaluation of C decreased from 14.3 percent in 2005 to 3.2 percent in 2007. Thus, it appears that the SASAC has issued more lenient ratings over time.

Table 2 shows the summary statistics for our sample of 63 SOEs from 2005 to 2007. The 25th percentile of SASAC scores is 125.7, which coincides with the cutoff score for B rated firms in 2007. The 75th percentile of SASAC scores is 132.0, which coincides with the cutoff score for A rated firms in 2007.

Empirical Models

Our hypotheses are summarized in Figure 2.

To test whether a positive association exists between the variables of interest and the SASAC evaluation results, we perform a set of regressions in which the dependent variables are the SASAC evaluation results. Evaluation results measures include evaluation scores, evaluation ratings, points earned on common measures, points earned on firm-specific measures, cutoff scores, upward adjustment of raw evaluation scores, and upward adjustment of evaluation ratings. We examine whether our political connection measures, geographic proximity measures, social responsibility measures, and political rank measures load significantly in addition to the control variables when explaining the variation of SASAC evaluation results. The general model specification is as follows:[11]

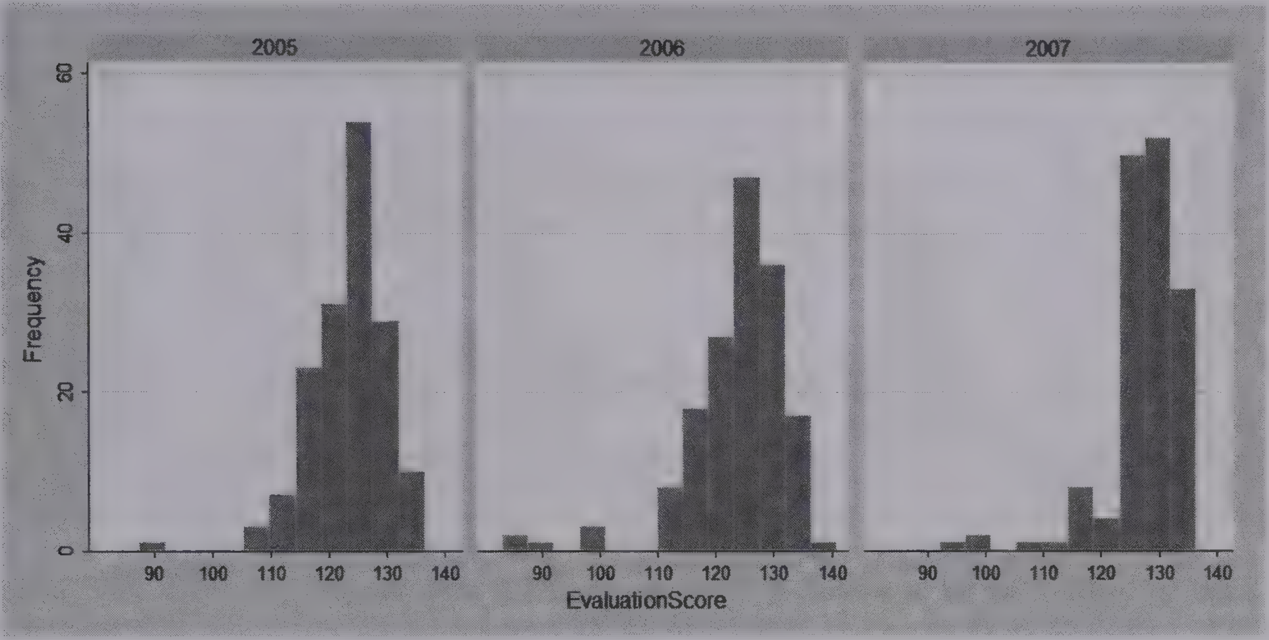
---

[10] A SASAC official told us that "[t]he SASAC shows favoritism to big firms due to strategic concerns, and having a larger asset base leads to a mechanical advantage when calculating the degree of operational difficulty, and thus large SOEs tend to get A's as long as they do OK jobs." The CFOs of relatively large SOEs mentioned that the SASAC has "done a great job" in giving big firms special opportunities, while the CFOs of relatively small SOEs said that the system is "unfair" knowing that largest firms are more likely to be leniently treated by the SASAC in the Performance Evaluation process. A CFO from a relatively small SOE mentioned that "A-ratings are reserved for those largest SOEs."

[11] The condition number generated from the Collin test of multicollinearity is 36.1684, which suggests the possibility of multicollinearity. The small sample size ($n = 168$) may exacerbate the multicollinearity concern for this study. Thus, we chose to introduce the independent variables one at a time instead of including all independent variables in the same regression. We also investigated whether a single common factor better reflects the underlying processes that created the correlations among our variables of interest. To this end, we performed principal factors extraction with varimax rotation in our research sample. Three factors were extracted with eigenvalues higher than 1. Consistent with our results, the social responsibility measures (*Employees*, *StrategicIndustry*) and SOE political rank measure load on the same factor, which we label Factor_Favoritism. *CFOConnection* and *Distance* load on a common factor, which we label Factor_Influence. *CEOConnection* loads on a factor, which we label Factor_CEO. We replaced the original independent variables with the factor scores in the regression models and the results are consistent with our original analyses.

FIGURE 1
Scores and Ratings Comparison of Sample Central Government Owned SOEs to the Population Central SOEs in 2005–2007[a]

Panel A: Population Distribution of Evaluation Scores of All 152 Central Government Owned SOEs in 2005–2007



---

[a] Figure 1 is excerpted and summarized from the *Report Regarding the Annual Performance Evaluation Results* of central government controlled SOEs issued by the Performance Evaluation Bureau of the SASAC in 2005–2007. The SASAC evaluated 160 central government controlled SOEs in 2005 and 2006, and evaluated 152 central government controlled SOEs in 2007.

(continued on next page)

$$\begin{aligned} Evaluation\ Results_{i,t} = {} & \alpha_0 + \beta_1 Variable\ of\ Interest_{i,t} + \beta_2 DegreeofDifficulty_{i,t} + \beta_3 Assets_{i,t} \\ & + \beta_4 EBT_{i,t} + \beta_5 ROE_{i,t} + \beta_6 INTurnover_{i,t} + \beta_7 ARTurnover_{i,t} \\ & + \beta_8 SalesGrowth_{i,t} + \varepsilon_{i,t}. \end{aligned}$$

We use OLS regression models and ordinal logit analyses to test whether our variables of interest lead to more lenient evaluation results. We use the OLS regressions to examine the effect that the variables of interest have on higher evaluation scores. We use the ordinal logit analyses to assess the effect of the variables of interest on the likelihood that SOEs belong to higher rating categories, and the likelihood that the SASAC upwardly adjusts SOEs scores and ratings.

Hypotheses Tests

Test of the Political Connections Hypothesis

Results for Model 1 in Column (1) of Tables 3 and 4 show that the CEO political connection measure (*CEOConnection*) is not significant. Results for Model 2 in Column (2) of Tables 3 and 4

FIGURE 1 (continued)

(continued on next page)

show that SOEs with politically connected CFOs are more likely to get higher evaluation scores (coefficient = 0.363; t-statistic = 2.49) and to get higher evaluation ratings (coefficient = 0.238; t-statistic = 1.99).[12] In terms of percentage change, there is a 27 percent increase in the odds of a SOE getting a higher evaluation rating for a one unit increase in the CFO political connection measure. These results provide partial support for the Political Connections Hypothesis (H1) that SOEs with politically connected executives are more likely to get higher evaluation scores (ratings). This finding is consistent with remarks made by interviewees that CFOs are the major firm representatives in communication with the SASAC, and that CEOs play lesser a role in influencing the SASAC evaluation results. For example, a SASAC official mentioned that CFOs typically take the responsibility for calling, visiting, and following up with the SASAC officials. Key inputs in the SASAC Performance Evaluation process include budgetary targets and financial statement bottom-line items, and CFOs often have specific knowledge about the generation of these numbers. This

---

[12] We use the degree of difficulty assigned to SOEs by the SASAC as a control variable because higher degree of operational difficulty parameters mechanically translate into higher evaluation scores/ratings in this research setting. Results do not change if this control is added or dropped.

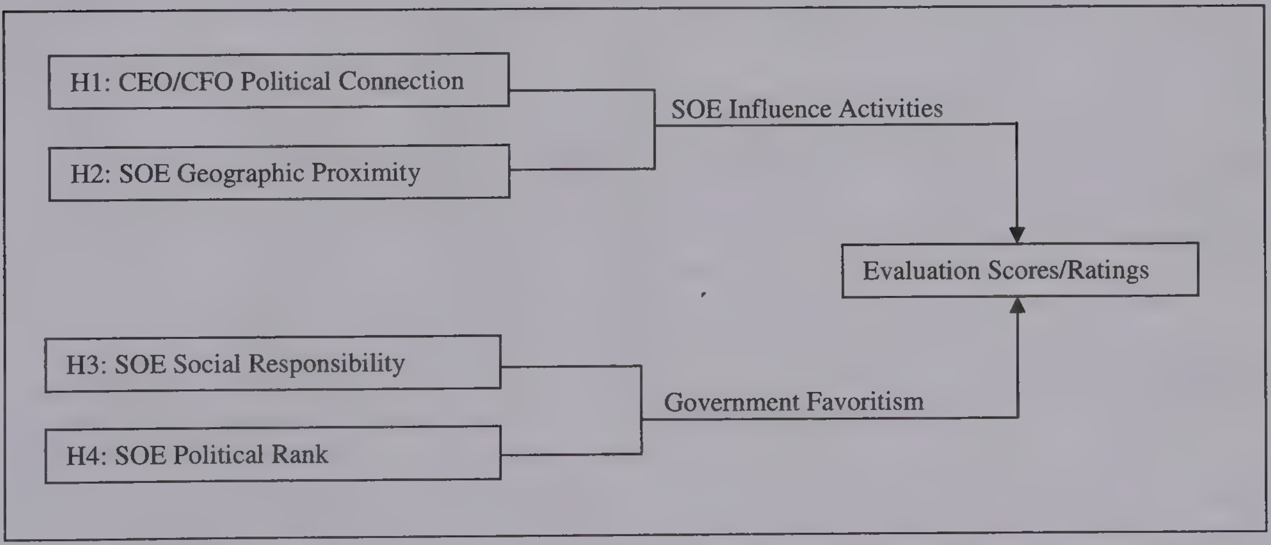
FIGURE 2
Summary of Hypotheses



H1: CEO/CFO Political Connection
H2: SOE Geographic Proximity
SOE Influence Activities
Evaluation Scores/Ratings
H3: SOE Social Responsibility
H4: SOE Political Rank
Government Favoritism

Figure 2 illustrates the hypotheses in this study. H1 is the political connections hypothesis: SOEs with executives with stronger political connections are more likely to get higher evaluation scores (ratings). H2 is the geographic proximity hypothesis: SOEs with headquarters located proximate to the SASAC central office are more likely to get higher evaluation scores (ratings). H3 is the social responsibility hypothesis: SOEs that assume more social responsibilities are more likely to get higher evaluation scores (ratings). H4 is the political rank hypothesis: SOEs with higher political ranks are more likely to get higher evaluation scores (ratings).

Columns (1)–(6) report results when *CEOConnection*, *CFOConnection*, *Distance* between the SASAC and SOE headquarters, SOE's number of employees, and SOE political rank are used respectively as independent variables. To ensure that our inferences are not artifacts of a few extreme values, all variables are winsorized at the top and bottom 1 percent. Regressions are performed with clustered robust standard errors (Rogers 1993) to control for within firm correlation. t-statistics are in parentheses.

result suggests that CFOs with strong political connections can successfully influence the SASAC's assignment of evaluation scores to their own advantage.

Test of the Geographic Proximity Hypothesis

Results for Model 3 in Column (3) of Tables 3 and 4 report that SOEs with headquarters located closer to the SASAC central office are more likely to get higher evaluation scores (ratings) with marginal significance ($p < 0.10$). These results are consistent with the prediction of the Geographic Proximity Hypothesis (H2), that SOEs with headquarters located closer to the SASAC central office are more successful in influencing the SASAC's decision in granting higher evaluation scores (ratings).

Test of the Social Responsibility Hypothesis

Results for Model 4 in Column (4) of Tables 3 and 4 show that the number of employees is not significantly related to evaluation scores or evaluation ratings. These results are not consistent with the Social Responsibility Hypothesis (H3). Results for Model 5 in Column (5) of Tables 3 and 4 suggest that firms competing in strategic industries do not receive higher evaluation scores for competing in strategic industries, as shown in Model 5, Table 3, but are more likely to belong to higher rating categories (coefficient = 1.479; t-statistic = 2.67) as shown in Model 5, Table 4. These results are consistent with the Chinese government not rewarding those SOEs that provide more employment opportunities with higher evaluation scores or ratings, but assigning higher evaluation ratings to SOEs in strategic industries.

Test of the Political Rank Hypothesis

Results for Model 6 shown in Column (6) of Table 3 show that SOEs with higher political rank are more likely to get higher evaluation scores (coefficient = 2.074; t-statistic = 4.29). Results for Model 6 in Column (6) of Table 4 show that SOEs with higher political rank are more likely to get higher evaluation ratings (coefficient = 3.596; t-statistic = 4.49). The results suggest that SOEs with higher political rank enjoy favorable treatment by obtaining higher degrees of difficulty, and can exert incremental influence in bargaining for higher evaluation scores after the parameter of degree of difficulty is set. In terms of economic significance, a one-unit increase in SOE political rank measure is associated with an increase of 2.0 points in the total evaluation score and a 3.6 increase in the log odds of being in a higher rating category. The results support the Political Rank Hypothesis, indicating that the SASAC favorably rates SOEs that help fulfill government officials' personal agendas.

Additional Analyses

In this section we conduct some additional analyses related to the how influence activities and favoritism could influence the target-setting process, the cutoff score assignment, and the *ex post* adjustments in evaluation scores and ratings.

The Association between Variables of Interest and the Target-Setting Process

Favoritism and influence costs can potentially occur at all five stages of the evaluation. In particular, it is possible that these variables affect the setting of the target in the first place. The target-setting process is a bottom-up process in which the SOEs propose annual operational targets and the SASAC either approves or adjusts those targets. Since the SASAC uses the difference between targeted amounts and actual budgeted amounts as a main parameter in score calculation, firms try to bargain for lower targets in the performance responsibility contract; a lower target assigned would mechanically lead to higher points earned.

To investigate the possibility that influence activities and government favoritism affect the target-setting process, we obtain detailed data regarding individual SOEs' points earned for achieving profit targets, points earned for achieving ROE targets, and points earned for achieving firm-specific targets. Profit targets and ROE targets, are common measures used by the SASAC to evaluate SOEs, while firm-specific targets may vary across firms. Previous research has found that only common measures affect superiors' holistic evaluations when both common measures and firm-specific measures are used in the Performance Evaluation process (Lipe and Salterio 2000). This occurs because common measures facilitate cross-sectional comparison and benchmarking. Superiors derive utility from power by favoring preferred subordinates (Prendergast and Topel 1996). At the same time, the psychological costs of confrontation inevitably arise when superiors are questioned by less-favored employees about the fairness of the evaluation system (Harris 1994; Bol et al. 2010). In our research setting, if the SASAC assigns a lower ROE common measure target to favored SOEs, then less-favored peer SOEs may question the fairness in target setting. One way for superiors to retain power and reduce the fairness concern is by setting lower targets for favored subordinates on specific measures but not on common measures. If this argument holds, then we expect to see that the variables of interest should load significantly on points earned by achieving firm-specific targets, and should not be significant when explaining the variation in points earned by achieving profit targets and points earned by achieving ROE targets.

The results in Panel A of Table 5 suggest that SOEs competing in strategic industries and having high political rank obtain fewer points on achieving targets based on common measures. On the other hand, the results in Panel B of Table 5 show that SOEs competing in strategic industries and having high political rank obtain more points on achieving targets based on firm-specific measures. This finding supports our conjecture that government favoritism leads to more slack in the target-setting process, but only in the target setting for firm-specific measures. Results are consistent with it being more difficult to manipulate the points earned on common measures rather than the points earned on SOE-specific measures. Common measures are comparable across different SOEs, making it more difficult (easier) for the government evaluator to favor a SOE by assigning lower targets on common (firm-specific) measures. Results also show that firms with high political rank are not necessarily those firms that are more profitable; rather, the data suggest that high-ranked firms have lower profitability compared to those SOEs with lower political rank. These results help to rule out the alternative explanation that the highly ranked SOEs get higher ratings because of their superior ability and performance.

The Association between Variables of Interest and Cutoff Score Assignment

We include SASAC scores as an additional control variable to examine whether the variables of interest influence the SASAC's decision of setting the cutoff scores to the advantage of individual SOEs, holding the evaluation scores constant. As shown in Model 2 in Column (2) of Table 6, the CFO political connections measure leads to a higher evaluation rating after controlling for the evaluation score (coefficient = 0.235; t-statistic = 1.82), suggesting that connected CFOs are better at bargaining with the SASAC for more advantageous cutoff scores for their own firms. SOEs whose headquarters are located closer to the central SASAC office get higher SASAC evaluation ratings, but this relation does not hold when SASAC evaluation scores are controlled for, implying that the geographic proximity does not contribute to effective manipulation of the SASAC's assignment of cutoff scores to the advantage of individual firms. Firms that compete in strategic industries receive higher SASAC evaluation ratings, and this relationship holds when evaluation scores are controlled for (coefficient = 1.390, t-statistic = 2.79), indicating that SOEs operating in

Table 6 reports the regression results for the effect of executive political connections, geographic proximity, SOE social responsibility, and SOE political rank on evaluation ratings after controlling for evaluation scores. To ensure that our inferences are not artifacts of a few extreme values, all variables are winsorized at the top and bottom 1 percent. Regressions are performed with clustered robust standard errors (Rogers 1993) to control for within firm correlation. t-statistics are in parentheses.

strategic industries may effectively influencing the SASAC's decision when setting cutoff scores to their own advantage. Political rank of SOEs (coefficient = 2.724, t-statistic = 4.13) remains positively and significantly related to higher evaluation ratings, suggesting that these firms can get more favorable ratings by influencing the determination of cutoff scores.

To address the question of how political connections and geographic proximity influence the assignment of cutoff scores, we ran a t-test between two subsamples of SOEs: the "just-above" SOEs and the "just-below" SOEs. A firm is included in the "just-above" subsample if it is among the five firms that received evaluation scores that are just higher than the cutoff score for a specific rating category. A firm is included in the "just-below" subsample if it is among the five firms that received evaluation scores that are just lower than the cutoff score for a specific rating category. Results (not tabulated) show that "just-above" SOEs have significantly higher level of political connections than "just-below" SOEs, indicating that political connections influence the SASAC's decision in assigning cutoff scores. An ordinal logit analysis (not tabulated) suggests that SOE political rank leads to a higher chance that an SOE belongs to the "just-above" cutoff score group.

Ex Post *Discretionary Adjustments in Evaluation Scores and Evaluation Ratings*

We investigate whether our variables of interest influence the *ex post* discretionary adjustment in evaluation scores and evaluation ratings after controlling for financial performance indicators. Recall from Section II that punishment points are deducted from raw scores if SOEs have severe safety-related incidents or if they are involved in financial fraud or scandals. Further, bonus points are awarded to those SOEs that have acquired financially distressed SOEs out of political concern. Since we do not have objective measurements of safety-related incidents, financial frauds or financial scandals, and political mergers and acquisitions, we only control for financial performance indicators. This limits the inferences we can draw from the results reported in Table 7 and Table 8.

Results for Model 2 shown in Column (2) of Tables 7 and 8 show that SOEs with strongly connected CFOs are more likely to receive upward score adjustments from the SASAC but not upward ratings adjustments. Results for Model 6 in Column (6) of Tables 7 and 8 suggest that SOEs with higher political rank are more likely to receive upward ratings adjustments but not upward scores adjustments.

Results for Model 4 detailed in Column (4) of Table 7 and Model 4 shown in Column (4) of Table 8 suggest that firms with more employees are less likely to get upward adjustment in scores and ratings. This observed negative association between employee number and *ex post* score/rating adjustment may occur because SOEs with more employees are harder to manage and more likely to evince safety-related incidents and financial fraud. When safety-related incidents and financial fraud do occur, SOEs with more employees receive more public attention and more media coverage, and it is more difficult for the SASAC to cover up these events in the Performance Evaluation process. Further, we use the domestic-listing status and cross-listing status as instrumental variables to proxy for organizational salience. We use the operational scope and the firm internal Herfindahl indices as instrumental variables to proxy for organizational complexity. Results (untabulated) show that even after controlling for these instrumental variables, the measure of employee number remains negatively and significantly related to ratings adjustments, possibly indicating that the Chinese government is rewarding SOEs for reducing extra manpower, but not for creating redundant job opportunities.

The Association between Variables of Interest and Future Financial Performance of SOEs

An alternative explanation that may account for the positive association between variables of interest and evaluation results is that political connections are unique resources, and that politically connected executives bring real benefits to these SOEs. Stronger political connections may reflect more formal and informal social ties and a higher level of legitimacy, capability, and social status. It is possible that the SASAC has specific knowledge regarding SOEs' political connections and makes reasonable adjustments by giving bonus points to those companies that make best use of their political connections in creating firm value. A lead-lag performance analysis (untabulated) shows that executive political connections and firm political rank are significantly and positively related to future evaluation scores, but are not significantly related to contemporaneous or future sales growth, ROE, and EVA. Thus, our data do not support the argument that political connections create value for SOEs or that the SASAC takes into consideration the real benefit of political connections of SOEs when granting evaluation scores and assigning evaluation ratings.

V. CONCLUSION AND DISCUSSION

The main objective of this study is to investigate the two-way process in which a subordinate and a superior engage in influence activities and favoritism, respectively, in subjective Performance Evaluation. To study this process we employ a database that contains information of economic importance from China, one of the world's largest economies. Our study suggests that the use of subjectivity in Performance Evaluation leads to influence activities, consistent with evaluators hesitating to use subjective evaluation even when objective measures are less than perfect. Furthermore, our interviews suggest that social interaction and unofficial communication between superiors and subordinates influence the level and direction of the subjective adjustment of Performance Evaluation scores. These results enrich our understanding of the complexity of social behavior in the Performance Evaluation process beyond the simple dichotomy of using objective versus subjective measures. Insights from the field also allow us to examine subjectivity in more detail. Subjectivity manifests itself in bargaining for lower operational targets, bargaining for upward adjustment of actual performance because of uncontrollable factors, bargaining for upward adjustment of raw scores, and by affecting the SASAC's determination of cutoff scores of ratings assignments.

We use social identity theory to identify factors that we expect to contribute to the effectiveness of influence activities such as persuasion and consultation in the subjective evaluation setting. Having CFOs with career histories as governmental officials and locating headquarters in geographical proximity to the evaluator (the SASAC office) facilitate the communication between the SOEs and the SASAC and, thus, lead to higher evaluation scores and ratings. This result contributes to the influence literature by demonstrating how subordinates' political connections and geographic proximity contributes to their SOEs' ability to influence the evaluation outcomes. We investigate the firm characteristics that lead to favorable governmental treatments in evaluation scores/ratings. Results indicate that the political rank of SOEs is positively and significantly related to the evaluation scores/ratings.

This study also addresses a puzzling question in the literature regarding why SEOs that receive more favorable governmental treatment perform worse than their counterparts in the private sector. Prior research has focused on the relationship between state ownership and firm value (Sapienza 2004; Dinc 2005), but has rarely discussed the mechanism used by the government that could distract SOEs from making value-maximizing decisions. Our empirical findings suggest that SOEs must balance multiple goals and make trade-offs between social responsibility and economic benefits, which leads to the use of multiple-measure Performance Evaluation when SOEs are evaluated. These social objective measures are hard to quantify and may conflict with one another. Subjectivity is then employed to strengthen incentives by incorporating additional information not included in objective measures. Given that the performance appraisal results influence SOE executives' compensation, promotion, and political career advancement, there are clear incentives for SOE executives to maximize measures officially included in the evaluation formula. However, when subjectivity is included in the appraisal process and when governmental officials are granted discretion in adjusting the evaluation scores/ratings, governmental evaluators can provide more favorable evaluation scores to those SOEs that comply. In addition, officials can treat larger SOEs with politically influential executives more favorably and, in return, hope for reciprocity from these executives who may later wish to advance their careers. Facing unfair treatment under subjective evaluation supervised by the government officials, SOE executives may divert their time and effort from maximizing firm value to pleasing government officials and, in the process, forgo business opportunities.

Our study has some limitations that may lead to future research. First, we follow Ittner et al. (2003) and Hoppe and Moers (2011) in trying to separate different types of subjectivity. We also show that subjectivity is manifested in several forms and is embedded in the Performance Evaluation system and in the target-setting process. Even though we distinguish our study by examining both influence activities and favoritism simultaneously, the correlation among the empirical proxies is likely to limit the study's ability to isolate these two constructs. Second, while our database derives from the Chinese government's evaluation of SOEs, future studies could be extended to the private sector in situations where the firm headquarters evaluates the performance of multiple business divisions.

APPENDIX A

SASAC Performance Evaluation System[a]

Measures	Base Points for Achieving Target	Range of Points	Points Granted	Degree of Difficulty (DoD)	Scores
Earnings before Tax and Extraordinary Items[b]	30	[24, 36]	P_EBT	[1.01, 1.14]	S_EBT = P_EBT × DoD when the preset target on EBT is achieved. Otherwise, the SOE just gets the points with no multiplier effect.
Return on Equity[c]	40	[32, 48]	P_ROE	[1.01, 1.14]	S_ROE = P_ROE × DoD when the preset target on ROE is achieved. Otherwise, the SOE just gets the points with no multiplier effect.
Inventory Turnover	15	[12, 18]	P_INTurn	[1.01, 1.14]	S_INTurn = P_ INTurn × DoD when the preset target on inventory turnover is achieved. Otherwise, the SOE just gets the points with no multiplier effect.
Accounts Receivable Turnover	15	[12, 18]	P_ARTurn	[1.01, 1.14]	S_ARTurn = P_ ARTurn × DoD when the preset target on accounts receivable turnover is achieved. Otherwise, the SOE just gets the points with no multiplier effect.
Sales Growth	15	[12, 18]	P_Growth	[1.01, 1.14]	S_Growth = P_Growth × DoD when the preset target on sales growth is achieved. Otherwise, the SOE just gets the points with no multiplier effect.
Subtotal: Objective	100	80–120			
Occurrence of Safety Incidents	0	$(-\infty, 0]$	P_Incidents		S_Incidents = P_S Incidents
Occurrence of Financial Frauds and Scandals	0	$(-\infty, 0]$	P_Frauds		S_Frauds = P_Frauds
Acquisition of Financially Distressed Firms Out of Political Concern	0	$[0, +\infty)$	P_Acquisition		S_Acquisition = P_Acquisition
Subtotal: Adjustments	0	$(-\infty, +\infty)$			
EvaluationScore	*Scores Based on Objective Measures + Scores Based on Discretionary Adjustments*				

---

[a] Appendix A is excerpted and summarized from the *Report Regarding the Annual Performance Evaluation* of central government controlled SOEs issued by the Performance Evaluation Bureau of the SASAC in 2003.

[b] An SOE can get one additional point when exceeding the preset EBT target by 3 percent.

[c] Additional points granted for exceeding the ROE target depend on the level of the preset target for ROE. When the preset target is lower than the historical record and the industry record, an SOE can get one additional point when exceeding the preset target by 4 percent. When the target is higher than or equal to the historical record or the industry record, an SOE can get one additional point when exceeding the preset target by 3 percent.

APPENDIX B
VARIABLE DEFINITIONS

Dependent Variables

$EvaluationScore_{it}$ = comprehensive Performance Evaluation score prepared by the SASAC assigned to SOE *i* in fiscal year *t*;

$EvaluationRating_{it}$ = rating assigned by the SASAC to SOE *i*. Evaluation ratings are 3 when SOEs are rated A, 2 when they are rated B, 1 when they are rated C, and 0 when they are rated D or E;

$Cutoff_{it}$ = dummy indicator that SOE *i* belongs to the "just-above" group of SOEs. An SOE is included in the "just-above" group if it is among the five firms that received evaluation scores that are just higher than the cutoff scores for the specific rating;

$DScoreAdj_{it}$ = *ex post* discretionary adjustment in evaluation scores. *DScoreAdj* is 2 if an SOE's final evaluation score is higher than the raw score, 1 if an SOE's final evaluation score equals the raw score, and 0 if an SOE's final evaluation score is lower than the raw score; and

$DRatingAdj_{it}$ = *ex post* discretionary adjustment in evaluation ratings. *DRatingAdj* is 2 if the SASAC adjust upward an SOE's rating based on discretionary adjustment in evaluation scores, 1 if the SASAC does not adjust an SOE's rating, and 0 if the SASAC adjust downward an SOE's rating.

Control Variables

$DegreeofDifficulty_{it}$ = degree of operational difficulties assigned by the SASAC to SOE *i*. This parameter, when multiplied by points earned, converts scores on separate financial performance measures of an individual SOE into its final comprehensive evaluation score;

$Assets_{it}$ = natural log of total assets of SOE *i* at the end of year *t*;

EBT_{it} = earnings before tax and extraordinary items of SOE *i* in year *t* scaled by total assets of SOE *i* in year *t*;

ROE_{it} = return on equity of SOE *i* in year *t*;

$INTurnover_{it}$ = operational cost divided by average inventory of SOE *i* in year *t*;

$ARTurnover_{it}$ = operational revenue divided by average accounts receivable of SOE *i* in year *t*; and

$SalesGrowth_{it} = (Sales_t - Sales_{t-1})$ divided by $Sales_{t-1}$ of SOE *i* in year *t*.

Political Connections

$CEOConnection_{it}$ = highest bureaucracy position a CEO occupied before joining an SOE top management team. The position is manually coded into two dimensions of categorical measures: the rank of the bureau in which the CEO had served, and the rank of the political title the CEO held. The ranking of the bureau is sorted into three categories: central government (= 3), provincial government (= 2), and municipal government (= 1). The ranking of the political title is also sorted into three levels, ministerial/provincial level (= 3), board/regional level (= 2), and unit level (= 1); and

$CFOConnection_{it}$ = coded as above for *CEOConnection*.

Geographic Proximity

$Distance_{it}$ = log transformation of distance between SOE headquarters and SASAC central office.

Social Responsibility

$Employees_{it}$ = natural log of the number of employee of SOE *i* scaled by *Assets* in fiscal year *t*; and

$StrategicIndustry_{it}$ = dummy of industry in which SOE *i* competes in year *t*. *StrategicIndustry* is coded as 1 when an SOE competes in industries in which the government wants to retain absolute control power, including the military, electric power, petroleum and petrochemicals, telecom, coal, civil aviation, and shipping and transportation; *StrategicIndustry* is coded as 0 when an SOE competes in industries not mentioned above.

Political Rank

$SOEPoliticalRank_{it}$ = political rank of the SOE *i* is located in fiscal year *t*. The SASAC sorts Chinese SOEs into three levels of administrative rank. *SOEPoliticalRank* is coded as 2 if an SOE is sorted into the highest administrative rank, coded as 1 if an SOE is sorted into the second highest administrative rank, and coded as 0 if an SOE is sorted into the third highest administrative rank.

Unintended Consequences of LIFO Repeal: The Case of the Oil Industry

David A. Guenther
University of Oregon

Richard C. Sansing
Dartmouth College and Tilburg University

ABSTRACT: This study examines the effect on firm value of repealing the last-in, first-out (LIFO) inventory method for tax purposes. Our model extends prior literature by determining quantities and prices in equilibrium, rather than specifying them exogenously. We find that LIFO repeal could increase the future after-tax cash flows of firms that had used LIFO, because the higher tax costs associated with FIFO result in lower equilibrium quantities and higher equilibrium output prices, which increase pretax cash flows. We illustrate our model by examining inventory methods used by firms in the oil industry.

Keywords: *LIFO; FIFO; tax incidence.*

I. INTRODUCTION

We examine the effects of repealing the last-in, first-out (LIFO) inventory method on firm production decisions, output prices, and firm after-tax profits. This is an important topic because repeal of LIFO, either directly or indirectly, as a consequence of adopting International Financial Reporting Standards (IFRS), is being considered by U.S. policymakers. Although our model applies to any industry, we discuss the implications of our model for the oil industry because (1) almost all firms in the industry use LIFO for their U.S. operations, and (2) demand for the oil industry's products is inelastic. Our model implies that LIFO repeal would cause the after-tax profits of firms in the oil industry to increase because (1) the higher marginal cost would reduce production and raise prices, and (2) inelastic demand implies that the higher output price would more than offset the higher tax cost associated with the first-in-first-out (FIFO) inventory method.[1]

We thank Andy Bernard, John Hand, Ken Njoroge, George Plesko, Bob Resutek, Jim Seida, Matt Slaughter, Mark Trombley, two anonymous reviewers, and workshop participants at Michigan State University, Tilburg University, and the 2009 American Taxation Association Midyear Meeting for helpful comments on an earlier version of this paper.

[1] In the absence of a transitional rule, repeal of LIFO would also cause firms to repay prior-year accumulated tax savings. Although our study does not address this effect, we discuss some implications in Section IV.

For nearly 20 years, Kang's (1993) "real value" model has influenced accounting research on the link between LIFO and firm value. The real value model implies that the value of the firm in the absence of inflation is the same as the value of the firm in the presence of inflation if the firm uses LIFO. LIFO provides a nominal tax gain, but not a real inflation-adjusted gain. This suggests that LIFO repeal would decrease the value of a firm that used LIFO. A critical assumption underlying the real value model is that neither inflation nor inventory method choice affects firms' production decisions or output prices. In this study, we relax that assumption, deriving equilibrium production decisions and prices instead of specifying them exogenously. We find that, unlike the results from the real value model, inflation and inventory choice can affect production decisions and firm value.

Our approach applies insights from the industrial organization literature regarding the effect of cost increases on production decisions and profits under Cournot competition.[2] In particular, an increase in costs, such as income taxes, that affects all firms in an industry induces all firms to reduce output, which, in turn, increases the equilibrium output price. Depending on the slope of an industry's marginal revenue curve, decreasing industry output quantity can either increase or decrease the profits and, hence, the value of the firms in the industry. If the industry marginal revenue curve is downward sloping, a cost increase causes the value of firms to decrease, because the higher selling price is not enough to offset the lost revenue from selling fewer units. In contrast, if the industry marginal revenue curve is upward sloping, a decrease in industry output results in an increase in industry total revenue, and this increase more than offsets the higher cost. Therefore, a cost increase causes the value of all firms in the industry to increase.

Nelson (1957) and Meyer (1967) identify situations in which increases in costs can lead to increased industry profits. The idea of increasing marginal revenue at the industry level may, at first, seem unrealistic. However, as Formby et al. (1982, 303) point out, "the conditions for a positively sloping marginal revenue curve are much less stringent than is generally recognized. Simple transformations of any well-behaved convex demand function can easily result in a demand for which marginal revenue is positively sloping. For this reason, positively sloping marginal revenue functions must be considered whenever convex demand functions are analyzed." In other words, the only restriction on increasing marginal revenue is that the demand curve must be convex.

An excise tax on inputs, such as the tax on the sale of domestically produced coal, is one example of a cost that affects all firms in an industry. Katz and Rosen (1985) and Seade (1985) show circumstances under which an increase in a tax can increase after-tax industry profits. Our study extends this idea to the effects of a firm's inventory method used for income tax purposes. When costs are increasing due to inflation, the use of FIFO instead of LIFO by all firms in an industry is economically equivalent to an excise tax on inputs imposed on all firms. Therefore, if the industry marginal revenue curve is increasing, all firms in an industry would have greater after-tax cash flows by using FIFO instead of LIFO. However, unlike an excise tax, firms can choose an inventory cost flow assumption (LIFO) that avoids the tax increase. Every firm would prefer for other firms to use FIFO while it chooses LIFO, getting both the tax benefits of LIFO for itself while also benefiting from the reduced quantities and higher prices associated with every other firm choosing FIFO. This can occur, for example, if a non-U.S. firm that is not permitted to use LIFO under home country tax rules competes in the same market with a U.S. firm that is permitted to use LIFO. Therefore, each firm has an incentive to choose LIFO, even in a situation in which every firm would be better off if every firm were to choose FIFO.

One way to have all firms use FIFO when doing so would increase the value of every firm is to no longer allow the use of LIFO for tax purposes in the U.S. This suggests that LIFO repeal would increase firm value if the industry's marginal revenue curve is upward sloping and all firms had adopted LIFO.

---

[2] Under Cournot competition, firms in an industry simultaneously make production decisions to maximize their own profits, under the assumptions that they know (1) the production decisions of their competitors, and (2) the industry demand curve.

By allowing inventory choice to affect production decisions and output prices, our model is in the spirit of Ball (1972, 25), who states:

> Many . . . accounting changes are associated with changes in other variables which affect cash flows. For example, unexpected increases in factor prices could trigger accounting changes to the LIFO method of inventory valuation, which in turn could reduce tax payments and perhaps increase stock market prices . . . Under the theory of perfect competition, we could even argue that product prices adjust until aftertax profits return to their former equilibrium.

Although the effect of LIFO on firm value has long been of interest to accounting researchers, the topic has recently taken on new importance for two reasons. First, the Obama administration's 2012 budget proposal contained a provision to eliminate LIFO for tax purposes, a proposal that was strongly opposed by a "LIFO coalition" of business interests (see http://www.savelifo.org). Second, the United States is currently moving toward harmonizing U.S. GAAP with International Financial Reporting Standards, under which LIFO is not an acceptable method. Because firms in the U.S. that use LIFO for tax purposes must also use LIFO for financial reporting purposes (Internal Revenue Code [IRC] §472(c)), adopting IFRS would eliminate LIFO for any firm required to use IFRS unless the conformity requirement in §472(c) were repealed. Thus, understanding the effects of LIFO on firm value is important in the context of both taxation and financial reporting standard setting.

In our model, firms operate in an imperfectly competitive environment. Each firm knows its industry's demand curve and input costs, and makes a Cournot conjecture regarding the production decisions of the other firms in the industry. Each firm in an industry chooses output quantity to maximize firm value by choosing its production quantity to equate the firm's after-tax marginal revenue and after-tax marginal cost, assuming that all other firms will set production levels in this same way.

We first consider the effects of LIFO repeal by comparing firm values when all firms use LIFO to firm values when all firms use FIFO. We find that all firms are worth more if all firms use FIFO than if all firms use LIFO if and only if the industry's marginal revenue curve is upward sloping. We illustrate this result in the special case of a demand function with constant own price elasticity, which allows us to relate our result to demand elasticity rather than to the slope of the marginal revenue curve. In this case, LIFO repeal would increase firm value when all firms use LIFO if and only if the demand function is inelastic. Next, we consider the general case in which some firms use LIFO and some firms use FIFO. In that case, LIFO firms benefit less from repeal, because the effect of LIFO repeal on output price is attenuated by the presence of FIFO firms. On the other hand, FIFO firms unequivocally benefit from LIFO repeal as long as some firms in the industry use LIFO.

We then apply our model to the oil industry, in which LIFO is widely used. Our model implies that LIFO repeal would induce lower output and higher prices of products such as gasoline. Because demand for gasoline is inelastic (Espey 1996), oil firms would earn higher after-tax profits in the U.S. as a consequence of LIFO repeal. We emphasize that this is an equilibrium outcome that the firms could not have achieved on their own, because each U.S. firm would maximize its own after-tax profits by using LIFO if all other firms choose FIFO.

Our paper highlights how financial reporting, taxation, and managerial accounting can each play a role in a firm's optimal inventory accounting method decision. Our model also highlights a rare instance in which a firm's financial reporting decision can change the firm's real production decisions through LIFO's effect on the marginal cost of production. Our main contribution is to show that LIFO repeal could increase the value of firms that had used LIFO because the higher tax costs associated with FIFO are mitigated and, in some cases, more than offset by the increase in pretax cash flows which occur due to lower equilibrium quantities and higher equilibrium output prices.[3]

Section II presents our model and shows how LIFO repeal would affect the value of LIFO firms if all firms use LIFO. In Section III, we show the effects of LIFO repeal on firm value if some firms use FIFO. Section IV shows how the inventory method choices by oil industry firms are consistent with our model, and examines the effects of LIFO repeal in that industry. Section V concludes.

II. A MODEL OF LIFO REPEAL

Economic Setting

We consider an industry with N identical firms making a single identical product. Both the cost and price associated with any particular output volume of this product increase each period at the inflation rate π. This is the type of cost increase assumed in Kang's (1993) real value model. On any date j, $j \in \{0, 1, 2, \ldots\}$, the cost of the product is $c(1+\pi)^j$ per unit. Because our analysis focuses on cost increases, we assume that nominal prices are weakly increasing (i.e., $\pi \geq 0$).

Each firm i produces q_i units of the product on each date j, and holds this same number of units in inventory between the date the units are produced (date j) and the subsequent period when the units are sold (date j+1). In other words, the q_i units sold by firm i on date j+1 were produced on date j and held in inventory between the two dates.

All products sold in an industry sell for the same price, P, which is a function of the aggregate quantity produced by the industry (Q) in the prior period, so price is a function of quantity, $P(Q)$. We assume that $P'(Q) < 0$ (i.e., demand is downward sloping). Each firm i pays income tax at rate τ on taxable income when the inventory is sold, where taxable income is equal to revenue, $q_i P(Q)$, less cost of goods sold. Recall that the firm holds q_i units of inventory between the date the units are produced and the date they are sold. If firm i uses the FIFO inventory method, its deduction for cost of goods sold on date j+1 is $c(1+\pi)^j$ per unit sold; if firm i uses the LIFO inventory method, its deduction for cost of goods sold on date j+1 is $c(1+\pi)^{j+1}$ per unit sold. We represent the deduction for cost of goods sold as $q_i c(1+\pi)^j(1+\lambda\pi)$, where $\lambda = 1$ if the firm uses LIFO, and $\lambda = 0$ if the firm uses FIFO. The real cost of capital for each firm is r, so the nominal discount factor is $(1+r)(1+\pi)$.

The present value of after-tax cash flows for the *industry* is maximized if all firms use LIFO and the quantity produced by the industry equates industry after-tax marginal revenue and after-tax marginal cost. However, if each firm strives to maximize the present value of its own after-tax cash flows, it will choose LIFO and a higher level of production than 1/Nth of optimal industry production. The reason is that one of the costs of firm i's higher production is a lower output price, and this cost is borne equally by all the firms in the industry. Therefore, if each firm strives to maximize its own profits, industry output will exceed the level at which industry-wide profits are maximized.

Because the firms are identical, we consider the case in which all firms in the industry use the same inventory method. To ensure that the second-order condition for firm profit maximization will be satisfied, we also assume that N is sufficiently large,[4] i.e.:

---

[3] Our results could also be applied to empirical studies of the valuation effect of LIFO adoption (e.g., Hand 1993), although this would require knowing the own price demand elasticities of the sample industries.

[4] This is the stability assumption made in Seade (1980).

$$N > -\frac{QP''(Q) + P'(Q)}{P'(Q)}. \tag{1}$$

When making the production decision for firm i at date j, the manager makes a conjecture regarding competitor firms' production decisions. The manager expects the selling price on date j+1 to be $P(Q)(1+\pi)^{j+1}$, $Q = q_i + \bar{q}(N-1)$, where $\bar{q}$ is the Cournot conjecture that the manager of firm i makes regarding its competitors' production decisions on date j.[5] Although firm i only chooses its own output, in a symmetric Cournot equilibrium, the industry produces $Q = q_iN$ units. Each manager chooses the firm's production quantity and inventory method in a non-cooperative fashion, maximizing the firm's own after-tax profit.

Equilibrium

We characterize firm value in two cases: (1) all firms use LIFO, and (2) all firms use FIFO. Firm i's profit maximization problem when producing on date j and selling on date j+1, framed in terms of the present value of future cash flows as of date j, is:

$$\max_{q_i}\left\{ q_i\left[\frac{P[q_i + \bar{q}(N-1)](1-\tau)(1+\pi)^{j+1}}{(1+r)(1+\pi)} - c(1+\pi)^j + \frac{\tau c(1+\pi)^j(1+\lambda\pi)}{(1+r)(1+\pi)}\right]\right\}. \tag{2}$$

Differentiating Expression (2) with respect to q_i and simplifying yields the first-order condition for profit maximization. Substituting q_i for $\bar{q}$ in the first-order condition reflects the manager's expectation that the production of the other firms in the industry will equal the production of firm i, resulting in $Q = Nq_i$. The equilibrium production quantity (q_i^*) for firm i on date j is the production that solves Equation (3):

$$q_i^* P'(Q)(1-\tau)(1+\pi) + P(Q)(1-\tau)(1+\pi) - c(1+\pi)(1+r) + \tau c(1+\lambda\pi) = 0. \tag{3}$$

The second-order condition for a maximum is satisfied because of Equation (1).

Equation (3) reveals that in an industry in which all firms use LIFO, inflation has no effect on output quantity because all of the $(1+\pi)$ terms factor out of Equation (3) when $\lambda = 1$. Therefore, using LIFO eliminates any effect that inflation would have on production decisions.

The solution to Expression (2) is the present value of the future cash flow resulting from the profit-maximizing production at time j. If we denote this solution to Expression (2) as Π, then the value (V) of the firm on date zero is:

$$V = \sum_{j=0}^{\infty} \frac{\Pi}{(1+r)^j(1+\pi)^j}. \tag{4}$$

If the firm uses LIFO ($\lambda = 1$), this expression simplifies to:

$$V_L = \frac{q_i^*\left[\Big(P(Q) - c\Big)(1-\tau) - rc\right]}{r}. \tag{5}$$

Because there is no π term in Equation (5), and because inflation does not affect the value of q_i^* for a LIFO firm, inflation has no effect on the value of the LIFO firm. If the firm uses FIFO ($\lambda = 0$), Equation (4) simplifies to:

---

[5] Because all firms in an industry are identical, the manager assumes that each firm's production decision will be the same.

$$V_F = \frac{q_i^*\left[\left(P(Q) - c\right)(1-\tau) - rc\right]}{r} - \frac{\tau c \pi q_i}{r(1+\pi)}. \tag{6}$$

We show how inflation affects firm value in our model when all firms use the same inventory method in Proposition 1.

Proposition 1: Comparing the value of a firm when inflation is positive to the value of the same firm when inflation is zero:

(a) If all firms in an industry use LIFO, the value of the firm is unchanged;
(b) If all firms in an industry use FIFO, the value of the firms will be higher if and only if $QP''(Q) + 2P'(Q) > 0$.

The proof is in Appendix A.

Proposition 1(a) is the same result as in Kang's (1993) "real value" model. Under these assumptions, electing LIFO does not change the value of a firm relative to what it was under FIFO with no inflation, because production decisions do not change. Proposition 1(b) reflects a known, albeit paradoxical, result from the industrial economics literature—under Cournot competition, an increase in costs, including tax costs, can increase the profits of all firms in an industry if the industry's marginal revenue curve is upward sloping. The intuition for this result is that if firms use FIFO, the increase in tax costs induces each firm to reduce its output, which, in turn, increases the equilibrium price. Because firms that strive to maximize their own profits produce at a higher level than the level at which industry profits are maximized, requiring all firms to use FIFO shifts output closer to the level that maximizes industry profits. If the condition $QP''(Q) + 2P'(Q) > 0$ is satisfied, the effect of reduced output on pretax profits more than offsets the higher tax costs associated with FIFO and, thus, all firms in the industry do better if all firms use FIFO than if all firms use LIFO.[6] We emphasize that it is not in the interest of any one firm to adopt FIFO unilaterally, because that firm would bear all of the increased tax costs, whereas the benefit from increased output price would be shared by all firms in the industry. Therefore, the increase in firm value associated with industry-wide adoption of FIFO cannot be achieved via unilateral action by one firm.

The term $[2P'(Q) + QP''(Q)]$ in Proposition 1(b) is the derivative of *industry* marginal revenue (*MR*), where $MR(Q) = QP'(Q) + P(Q)$ and $MR'(Q) = QP''(Q) + 2P'(Q)$. As long as the industry demand curve is convex, the slope of the industry marginal revenue curve could be positive or negative. If industry marginal revenue is decreasing, inflation decreases the value of a FIFO firm. In contrast, if industry marginal revenue is increasing, inflation increases the value of a FIFO firm.

Industry marginal revenue could behave in various ways. In the case of a linear demand curve, industry marginal revenue is decreasing in Q. In the case of a demand curve with constant price elasticity of demand, industry marginal revenue is positive and decreasing in Q if demand is elastic and is negative, and increasing in Q if demand is inelastic. Firm value is increasing if all firms adopt FIFO when demand is inelastic, because negative marginal revenue implies that a decrease in industry output results in an increase in industry total revenue, such that the higher total revenue more than offsets the higher tax cost from FIFO.[7] Formby et al. (1982, 303) point out that "simple transformations of any well-behaved convex demand function can easily result in a demand for which marginal revenue is positively sloping."

---

[6] Although industry after-tax profits and tax revenues increase, consumer surplus decreases by an even greater amount. This occurs because consumers pay higher prices and there is a decrease in consumer surplus associated with the reduction in quantity.

[7] The demand for the product is elastic if the percentage change in price is less than the percentage change in quantity; the demand for the product is inelastic if the percentage change in price is greater than the percentage change in quantity.

The implication of Proposition 1 is that LIFO repeal could increase or decrease firm value. When $\pi = 0$, LIFO and FIFO firms have the same value. For higher values of π, the value of LIFO firms does not change; the value of FIFO firms could increase or decrease, depending on the slope of the industry marginal revenue curve. Therefore, if the industry marginal revenue curve is increasing, LIFO repeal would increase firm value.

Example

We illustrate Proposition 1 using as an example a demand function that exhibits constant price elasticity of demand. The selling price on date j+1 is:

$$P(Q) = \frac{d(1+\pi)^{j+1}}{Q^{1/\varepsilon}}, \tag{7}$$

where $d > 0$ and $\varepsilon > 0$ are exogenous demand parameters. Expressing quantity as a function of price yields:

$$Q(P) = \left[\frac{d(1+\pi)^{j+1}}{P}\right]^{\varepsilon}. \tag{8}$$

The price elasticity of demand, $E(Q)$, is:

$$E(Q) \equiv \frac{\partial Q}{\partial P}\frac{P}{Q} = -\varepsilon, \tag{9}$$

which is constant for this demand function. If $\varepsilon > 1$, the demand for the product is elastic; i.e., the percentage change in price is less than the percentage change in quantity. If $\varepsilon < 1$, the demand for the product is inelastic; i.e., the percentage change in price is greater than the percentage change in quantity.

Using Expression (2), the manager of firm i chooses q_i on date j to solve:

$$\max_{q_i}\left\{ q_i\left[\frac{P[q_i+\bar{q}(N-1)](1-\tau)}{(1+r)(1+\pi)} - c(1+\pi)^j + \frac{\tau c(1+\pi)^j(1+\lambda\pi)}{(1+r)(1+\pi)}\right]\right\}. \tag{10}$$

To solve for the equilibrium quantities under LIFO and FIFO, differentiate Expression (10) to find the first-order condition for each firm. As each firm faces the same production decision problem, and all firms in an industry are identical, we substitute $q_i = \bar{q}$ into the first-order condition to find the equilibrium production quantity for firm i on date j. When all firms in the industry use LIFO, the optimal production quantity is:

$$q^*_{iL} = \frac{1}{N}\left[\frac{(1-\tau)d(\varepsilon N-1)}{c\varepsilon N(1+r-\tau)}\right]^{\varepsilon}. \tag{11}$$

The second-order condition is satisfied because the condition in Equation (1) implies that $N > \frac{1}{\varepsilon}$. The optimal production quantity for a LIFO firm is not affected by the inflation rate π.

When all firms in the industry use FIFO, the corresponding equilibrium quantity is:

$$q^*_{iF} = \frac{1}{N}\left[\frac{(1-\tau)d(1+\pi)(\varepsilon N-1)}{c\varepsilon N\{(1+r)(1+\pi)-\tau\}}\right]^{\varepsilon}. \tag{12}$$

Note that when $\pi = 0$, the optimal output quantity is the same under both LIFO and FIFO.

The cash outflow per unit from production on date j is the same for firms using either LIFO or FIFO, and is equal to $c(1+\pi)^j$, so total cash outflow for a firm using LIFO is:

$$q_{iL}^*[c(1+\pi)^j]. \tag{13}$$

For a firm using LIFO, the after-tax cash inflow on date $j+1$ from selling products that were produced on date j is:

$$q_{iL}^*\left[\frac{(1-\tau)d(1+\pi)^{j+1}}{(Nq_{iL}^*)^{1/\varepsilon}} + \tau c(1+\pi)^{j+1}\right]. \tag{14}$$

Using a discount factor of $(1+r)(1+\pi)$, the value of the firm on date zero when all firms in the industry use LIFO is:

$$V_L = \sum_{j=0}^{\infty} q_i^*\left[\frac{(1-\tau)d}{(Nq_{iL}^*)^{1/\varepsilon}(1+r)^{j+1}} + \frac{\tau c}{(1+r)^{j+1}} - \frac{c}{(1+r)^j}\right]. = \frac{c(1+r-\tau)\left[\frac{d(\varepsilon N-1)(1-\tau)}{c\varepsilon N(1+r-\tau)}\right]^{\varepsilon}}{N(\varepsilon N-1)r}. \tag{15}$$

The value of the LIFO firm is not affected by the inflation rate π.

For a firm using FIFO, the after-tax cash inflow on date $j+1$ from selling products that were produced on date j is:

$$q_{iF}^*\left[\frac{(1-\tau)d(1+\pi)^{j+1}}{(Nq_{iF}^*)^{1/\varepsilon}} + \tau c(1+\pi)^{j}\right]. \tag{16}$$

The only difference between Expressions (16) and (14) is the value of the tax savings, $\tau c(1+\pi)^j$, rather than $\tau c(1+\pi)^{j+1}$. Using a discount factor of $(1+r)(1+\pi)$, the value of the firm on date zero when all firms in the industry use FIFO is:

$$\begin{aligned} V_F &= \sum_{j=0}^{\infty} q_{iF}^*\left[\frac{(1-\tau)d}{(Nq_{iF}^*)^{1/\varepsilon}(1+r)^{j+1}} + \frac{\tau c}{(1+r)^{j+1}(1+\pi)} - \frac{c}{(1+r)^j}\right] \\ &= \frac{c\{(1+r)(1+\pi)-\tau\}\left[\frac{d(1+\pi)(\varepsilon N-1)(1-\tau)}{c\varepsilon N\{(1+r)(1+\pi)-\tau\}}\right]^{\varepsilon}}{N(\varepsilon N-1)(1+\pi)r}. \end{aligned} \tag{17}$$

If inflation is zero ($\pi = 0$), the value of the FIFO firm in Equation (17) is the same as the value of the LIFO firm in Equation (15).[8] However, with positive inflation ($\pi > 0$), the value of the FIFO firm relative to the value of the LIFO firm is given by the ratio V_F/V_L:

$$\frac{V_F}{V_L} = \left[\frac{(1+\pi)(1+r-\tau)}{(1+\pi)(1+r)-\tau}\right]^{\varepsilon-1}. \tag{18}$$

The term in brackets is less than 1, so the ratio itself is less than 1 if $\varepsilon > 1$, and greater than 1 if $\varepsilon < 1$. Therefore, assuming positive inflation, if the industry has a demand curve that exhibits constant price elasticity of demand, and demand is elastic, firm value is higher under LIFO, the same result that Kang (1993) and Hand (1993) report. However, contrary to the results from Kang's (1993) model, when we allow inflation to affect output quantities, firm value is higher under FIFO than LIFO when demand is inelastic.[9]

---

[8] Equations (15) and (17) are equivalent to Equations (5) and (6) for the demand curve given by Equation (8).

[9] Firm value is unaffected by inventory method choice when $\varepsilon = 1$.

Using this particular demand curve, in which demand exhibits constant price elasticity, inelastic demand ($\varepsilon < 1$) is a sufficient condition to arrive at the general result from Proposition 1(b) that $\frac{\partial V_F}{\partial \pi} > 0$; i.e., inflation increases the value of a FIFO firm if and only if $2P'(Q) + QP''(Q) > 0$. We explore the intuition behind this condition by examining the properties of the industry revenue curve, $R(Q) = QP(Q)$. Taking the derivative yields the marginal revenue for the industry:

$$MR(Q) = QP'(Q) + P(Q). \tag{19}$$

Rearranging terms and using Equation (9) yields:

$$MR(Q) = P(Q)\left[1 + \frac{1}{E(Q)}\right], \tag{20}$$

where $E(Q) < -1$ when demand is elastic, and $E(Q) > -1$ when demand is inelastic. Therefore, $MR(Q)$ is negative if demand is inelastic and positive if demand is elastic. Differentiating Equation (20) with respect to Q and noting that $E(Q)$ is equal to $-\varepsilon$, a constant, in our example yields:

$$MR'(Q) = P'(Q)\left[1 - \frac{1}{\varepsilon}\right]. \tag{21}$$

Therefore, in our example, the slope of the industry marginal revenue curve is positive when demand is inelastic ($\varepsilon < 1$), and is negative when demand is elastic ($\varepsilon > 1$). This means that for firms in industries with inelastic demand, a mandated switch to FIFO increases after-tax industry profits due to a reduction in industry production that yields an increase in price and an increase in total industry revenue.

III. EFFECTS OF LIFO REPEAL IF SOME FIRMS USE FIFO

In this section, we illustrate the case in which some firms choose LIFO and others choose FIFO. We assume that different firms make different inventory method choices for reasons external to the model, such as facing different costs of adopting LIFO or different preferences regarding the use of LIFO for financial reporting purposes. In this section, we consider the effects of LIFO repeal on firm value when, prior to repeal, M of the firms in an industry use LIFO and the remaining N-M firms use FIFO.

As demonstrated in Section II, the effect of LIFO repeal on the value of a LIFO firm when all firms use LIFO is a combination of two effects; the tax effect reduces firm value, but the effect of reduced supply on output price increases firm value. Which effect dominates depends on the slope of industry marginal revenue. When some firms use FIFO, the tax effect of LIFO repeal remains for the LIFO firms, but the effect on price is attenuated because the FIFO firms were already producing at a reduced level. Therefore, the effect of LIFO repeal on the value of LIFO firms is less favorable when some firms already use FIFO. In contrast, FIFO firms always benefit from LIFO repeal; their tax treatment does not change, but they benefit from the increased output price that occurs when LIFO firms must switch to FIFO.

We illustrate these effects for an example case in which the industry faces a linear demand function. The selling price on date j+1 is:

$$P(Q) = (1 + \pi)^{j+1}(d - aQ), \tag{22}$$

where $d > c(1 + r)$ and $a > 0$ are exogenous demand parameters.[10]

---

[10] The industry marginal revenue curve is always downward sloping when demand is linear.

A firm that uses LIFO chooses q_L on date j to solve:

$$\max_{q_L}\left\{ q_L \left[\begin{array}{l} \dfrac{(1+\pi)^{j+1}\left(d - a[q_L - (M-1)\bar{q}_L - (N-M)\bar{q}_F]\right)(1-\tau)}{(1+r)(1+\pi)} \\ -c(1+\pi)^j + \dfrac{\tau c(1+\pi)^{j+1}}{(1+r)(1+\pi)} \end{array} \right] \right\}. \tag{23}$$

A firm that uses FIFO chooses q_F on date j to solve:

$$\max_{q_F}\left\{ q_F \left[\begin{array}{l} \dfrac{(1+\pi)^{j+1}\left(d - a[q_F - M\bar{q}_L - (N-M-1)\bar{q}_F]\right)(1-\tau)}{(1+r)(1+\pi)} \\ -c(1+\pi)^j + \dfrac{\tau c(1+\pi)^{j}}{(1+r)(1+\pi)} \end{array} \right] \right\}. \tag{24}$$

To solve for the equilibrium quantities, we differentiate Expressions (23) and (24) to arrive at the first-order condition for each firm, then substitute q_F for $\bar{q}_F$ and q_L for $\bar{q}_L$ into the first-order conditions to find the equilibrium production quantity for each type of firm on date j. Firms that use LIFO choose:

$$q_L^* = \frac{d - c(1+r-\tau)}{a(1+N)} + \frac{c\tau\pi(N-M)}{a(1+N)(1+\pi)}. \tag{25}$$

Firms that use FIFO choose:

$$q_F^* = \frac{d - c(1+r-\tau)}{a(1+N)} - \frac{c\tau\pi(1+M)}{a(1+N)(1+\pi)}. \tag{26}$$

Substituting the quantities from Equations (25) and (26) into Expressions (23) and (24) yields the present value on date j of after-tax cash flows associated with production on date j and sales on date $j+1$:

$$\Pi_L = \frac{(1+\pi)^{j-2}\{[d - c(1+r-\tau)](1+\pi) + c\tau\pi(N-M)\}^2}{a(1+N)^2(1+r)}; \tag{27}$$

$$\Pi_F = \frac{(1+\pi)^{j-2}\{[d - c(1+r-\tau)](1+\pi) - c\tau\pi(1+M)\}^2}{a(1+N)^2(1+r)}. \tag{28}$$

Therefore, the values of the respective firms prior to LIFO repeal are:

$$V_L = \sum_{j=0}^{\infty} \frac{\Pi_L}{(1+r)^j(1+\pi)^j} = \frac{\{[d - c(1+r-\tau)](1+\pi) + c\tau\pi(N-M)\}^2}{r(1+\pi)^2 a(1+N)^2}, \tag{29}$$

and:

$$V_F = \sum_{j=0}^{\infty} \frac{\Pi_F}{(1+r)^j(1+\pi)^j} = \frac{\{[d - c(1+r-\tau)](1+\pi) - c\tau\pi(1+M)\}^2}{r(1+\pi)^2 a(1+N)^2}. \tag{30}$$

After LIFO repeal, all N firms use FIFO and, thus, all have value V:

$$V = \frac{\{[d - c(1+r-\tau)](1+\pi) - c\tau\pi(1+N)\}^2}{r(1+\pi)^2 a(1+N)^2}. \tag{31}$$

Because *N-M* firms use FIFO, Equation (29) implies that V_L is increasing in the number of FIFO firms and, thus, the effect of LIFO repeal on the value of LIFO firms is less favorable as the number of FIFO firms increases. In contrast, comparing Equations (30) and (31) shows that FIFO firms benefit from LIFO repeal unless all firms in the industry already use FIFO.

IV. INVENTORY CHOICE IN THE OIL INDUSTRY

We illustrate the implications of our model of LIFO repeal by examining the oil industry, SIC 2911 Petroleum Refining. We choose the oil industry for several reasons. First, LIFO is widely used by corporations that supply the U.S. market for refined petroleum products. Second, economists have studied the demand for the outputs of this industry, including gasoline, extensively. They estimate demand to be inelastic with respect to price, with an upward sloping marginal revenue curve at the industry level. Third, repeal of LIFO for oil companies only was proposed in 2006 to pay for a reduction in the federal excise tax on gasoline. The Wyden-Gregg tax reform bill proposed in 2010 also proposed LIFO repeal for oil companies. The Obama administration's 2012 budget proposal also included repeal of LIFO for all firms. About 65 percent of the U.S. market for refined petroleum products is provided by five U.S. firms—ConocoPhillips, ExxonMobil, Valero Energy, Chevron, and Marathon Oil (Molavi 2011). The first Compustat inventory method code listed for each of these five firms for 2009 is LIFO.[11] For 2009, Compustat lists 15 firms incorporated in the U.S. with SIC code 2911 (Petroleum Refining), and for 14 of these firms the first inventory method code listed is LIFO. The exception, Murphy Oil Corporation, had $335 million of inventory valued at LIFO in 2009, out of total inventory of $734 million. There was a $551 million reserve associated with its LIFO inventory, however, suggesting that the reason LIFO is not shown as the first inventory method code for Murphy Oil is the low historical cost of its LIFO inventory.

Roughly 15–20 percent of the U.S. market is represented by U.S. subsidiaries of foreign corporations; for example, Shell Oil Company is owned by Royal Dutch Shell. Although Royal Dutch Shell uses International Financial Reporting Standards, which do not allow LIFO, Revenue Ruling 78-246 allows U.S. subsidiaries of foreign corporations to use LIFO even though the consolidated financial statements use FIFO. Turgeon et al. (2009) report that many U.S. subsidiaries with foreign parents use LIFO without violating the conformity requirement. We conclude that nearly all firms in the Petroleum Refining industry use LIFO with respect to their U.S. operations.

Consider what would happen to firms in the oil industry if LIFO were repealed for U.S. tax purposes. Assuming positive inflation, U.S. firms or U.S. subsidiaries of foreign firms currently using LIFO would face an increase in their marginal costs, which would induce them to reduce output, which, in turn, would increase the sales price of their products. Because products such as gasoline exhibit inelastic demand, the increase in after-tax income due to the higher sales price would exceed the decrease in after-tax income due to lower sales volume and higher tax costs. Therefore, our model predicts that LIFO repeal would increase the future after-tax cash flows of firms in the oil industry. We emphasize that absent collusion, the same firms cannot achieve this outcome on their own by voluntarily switching to FIFO, because each firm would maximize its own after-tax profits by using LIFO, even though all firms in the industry are better off if they all use FIFO.

We conclude this section by estimating the increase in the value of U.S. oil companies if LIFO were to be repealed, and comparing it to the potential tax liability on the firms' existing LIFO reserves. Using the long-run price elasticity of demand for gasoline of –0.58 (Espey 1996), the average inflation rate since 1971 of 4.4 percent, a cost of capital of 10 percent, and a tax rate of 35 percent, Equation (18) implies that the value of the oil industry's assets would increase by about 0.82 percent if LIFO were repealed and the repeal affected the value of all of the industry's assets. This is an upper bound on the increase in value because these are multinational firms; sales in foreign jurisdictions would not be affected by LIFO repeal.[12] The 15 U.S. companies in SIC 2911 had a market value of assets, computed as the market value of equity plus the book value of liabilities, of about $1.2 trillion.

---

[11] According to the Compustat manual, the order in which inventory method codes are listed reflects the relative amounts of a firm's inventory valued under each method, with the first method listed reflecting the method used for the largest portion of the firm's inventory.

The LIFO reserves of these 15 companies in 2010 were about $54.4 billion. Whether and how this amount would be included in taxable income is an open question. The Obama administration's proposal is to recognize the LIFO reserve as taxable income ratably over ten years. Using a discount rate of 10 percent and a tax rate of 35 percent, the present value of tax on the oil industry's LIFO reserves is about $13 billion, or about 1 percent of the industry's assets.

V. CONCLUSION

Our study extends Kang's (1993) "real value" model of the effect of LIFO on firm value by allowing an industry's output quantity and product price to be determined endogenously, so that both are affected by inventory method choices made by firms in the industry. With positive inflation, inventory method choice for tax purposes affects optimal output quantities, setting marginal cost equal to marginal revenue, because the additional tax cost under FIFO affects a firm's marginal cost.

The ability to use LIFO for U.S. tax purposes could be eliminated in the future, either by Congress changing the tax law or by U.S. standard setters adopting IFRS. Our results imply that the effect of LIFO repeal on firm value could have unexpected results. We find that for some industries, the value of LIFO firms would increase due to LIFO repeal, because the repeal would force firms to use FIFO in industries in which all firms would be worth more if all firms chose FIFO, but each firm individually has an incentive to use LIFO. In the case of an industry facing a demand curve with constant price elasticity, LIFO repeal would increase firm value if demand is inelastic.

We illustrate our model by examining the oil industry, in which LIFO is widely used by both U.S. firms and U.S. subsidiaries of foreign firms. Products produced by the oil industry, such as gasoline, have inelastic demand. We find that LIFO repeal would have the unintended consequence of increasing the after-tax profits of firms in the oil industry by raising marginal cost, such that the reduction in output and the corresponding increase in output price would outweigh the higher tax cost associated with FIFO.

APPENDIX A

PROOF OF PROPOSITION 1

(a) From Equation (3), we know that q_i^* is unaffected by π when all firms choose LIFO. All other terms in Equation (5) are exogenous constants, so firm value is not affected by π when all firms choose LIFO.

(b) To see how inflation affects the value of a FIFO firm, we first differentiate Equation (6) with respect to the inflation parameter π:

$$\frac{\partial V_F}{\partial \pi} = \frac{q_i[P'(Q)N(1-\tau)]}{r}\frac{\partial q_i}{\partial \pi} + \frac{[P(Q)-c](1-\tau)-rc}{r}\frac{\partial q_i}{\partial \pi} - \frac{q_i \tau c}{r(1+\pi)^2} + \frac{\tau c \pi}{r(1+\pi)}\frac{\partial q_i}{\partial \pi}. \quad \text{(A1)}$$

To determine $\frac{\partial q_i}{\partial \pi}$, we represent the first-order condition in Equation (3) as $F(q_i, \pi) = 0$, substitute $Q = Nq_i$, then implicitly differentiate F to yield:

$$F_{q_i} = (1-\tau)(1+\pi)[q_i P''(Q)N + P'(Q) + NP'(Q)]; \quad \text{(A2)}$$

$$F_{\pi} = q_i P'(Q)(1-\tau) + P(Q)(1-\tau) - c(1+r); \quad \text{(A3)}$$

$$\frac{\partial q_i}{\partial \pi} = -\frac{F_\pi}{F_{q_i}} = -\frac{q_i P'(Q)(1-\tau) + P(Q)(1-\tau) - c(1+r)}{(1+\pi)(1-\tau)[QP''(Q) + (1+N)P'(Q)]}. \quad \text{(A4)}$$

Substituting the value of $\frac{\partial q_i}{\partial \pi}$ from Equation (A4) into Equation (A1), using the result from Equation (3) that:

$$c = \frac{(1+\pi)(1-\tau)[P(Q) + q_i P'(Q)]}{(1+\pi)(1+r) - \tau(1+\lambda\pi)},$$

and simplifying yields:

$$\frac{\partial V_F}{\partial \pi} = -\frac{Q\tau(1-\tau)[NP(Q) + QP'(Q)][2P'(Q) + QP''(Q)]}{rN^2(1+\pi)[(1+\pi)(1+r) - \tau][(1+N)P'(Q) + QP''(Q)]}. \quad \text{(A5)}$$

The effect of inflation on the value of a FIFO firm depends on the sign of Equation (A5). To determine the sign of Equation (A5), we first consider the term $[NP(Q) + QP'(Q)]$ in the numerator. Firm i's revenue (R) is equal to $q_i P(Q)$, and marginal revenue ($\partial R/\partial q_i$) is equal to $q_i P'(Q) + P(Q)$. Multiplying marginal revenue by N results in $Nq_i P'(Q) + NP(Q)$, which is equal to $QP'(Q) + NP(Q)$ because $Q = Nq_i$. Therefore, $[NP(Q) + QP'(Q)]$ is the product of N and the marginal revenue of firm i, which is positive because each firm equates its own marginal revenue with its own marginal cost. The term $[(1+N)P'(Q)+QP''(Q)]$ in the denominator of Equation (A5) is strictly negative because of Equation (1). Therefore, the sign of Equation (A5) is the same as the sign of the term $2P'(Q)+QP''(Q)$.

Do IRS Audits Deter Corporate Tax Avoidance?

ABSTRACT: We extend research on the determinants of corporate tax avoidance to include the role of Internal Revenue Service (IRS) monitoring. Our evidence from large samples implies that U.S. public firms undertake less aggressive tax positions when tax enforcement is stricter. Reflecting its first-order economic impact on firms, our coefficient estimates imply that raising the probability of an IRS audit from 19 percent (the 25th percentile in our data) to 37 percent (the 75th percentile) increases their cash effective tax rates, on average, by nearly two percentage points, which amounts to a 7 percent increase in cash effective tax rates. These results are robust to controlling for firm size and time, which determine our primary proxy for IRS enforcement, in different ways; specifying several alternative dependent and test variables; and confronting potential endogeneity with instrumental variables and panel data estimations, among other techniques.

We appreciate comments on an earlier version of this paper, which had been circulated under the title, "IRS Monitoring, Corporate Tax Avoidance, and Governance in Public Firms," from Sutirtha Bagchi, Beth Blankespoor, Scott Dyreng, Michelle Hanlon, David Kenchington, Clive Lennox, Russell Lundholm, Landon Mauler, Kenneth Merkley, Greg Miller, Lil Mills, Tom Omer, Ed Outslay (a discussant), Nemit Shroff, Joel Slemrod, Brian Spilker, and Gwen Yu. We thank the Tax Executive Institute for providing valuable insights through our survey. We also thank participants at the 2009 BYU Accounting Research Symposium, the Kapnick Workshop at the University of Michigan, and the 2010 ATA Midyear Meeting. We also thank Susan Long of the Transactional Records Access Clearinghouse and Ruth Schwartz of the Statistical Information Service of the IRS for their help in gathering institutional knowledge and data regarding the IRS and its information systems. Jeffery Hoopes gratefully acknowledges funding from the Harry Jones Fund for Earnings Quality, the Paton Fellowship, and the Deloitte Foundation. Professor Pittman acknowledges funding from the CMA Professorship and Canada's Social Sciences and Humanities Research Council.

Editor's note: Accepted by John Harry Evans III, with thanks to Thomas Omer for serving as editor on a previous version.

I. INTRODUCTION

Recent evidence implies that natural byproducts of tough corporate tax enforcement include lower managerial diversion (e.g., Desai and Dharmapala 2006, 2009; Desai et al. 2007), improved earnings quality (e.g., Hanlon et al. 2011), and valuable cross-monitoring evident in debt (e.g., Guedhami and Pittman 2008) and equity (e.g., El Ghoul et al. 2011) pricing. However, extant research neglects to examine the more primitive issue of whether tax enforcement disciplines firms by constraining their tax avoidance. We bridge this gap by providing evidence on whether public firms undertake less aggressive tax positions when the expected likelihood of an Internal Revenue Service (IRS) audit is higher.

Firms are understandably eager to invest in tax planning to lower their taxes since this benefits shareholders as the residual claimants (e.g., Mills 1996; Mills et al. 1998). However, firms also consider the costs stemming from aggressive tax avoidance strategies, including the economically material fines, interest, and penalties that the IRS can impose for under-reporting (Wilson 2009). In this paper, we evaluate whether tax avoidance subsides when corporate tax enforcement is better. Although this prediction may initially appear intuitive, there are several reasons to suspect that corporate tax avoidance is insensitive to IRS oversight. In particular, managers may not perceive IRS audits as sufficiently costly (Hanlon et al. 2007), or may have little incentive to reduce their cost (Slemrod 2004; Graham et al. 2005; Armstrong et al. 2012). Also, irrespective of the severity of IRS enforcement, firms may refrain from drastically lowering their taxes in order to avoid potential political costs stemming from being labeled as tax aggressive (e.g., Hanlon and Slemrod 2009; Mills et al. 2010).

Moreover, firms may behave like wealthy individuals by increasing tax avoidance when IRS monitoring is stricter to ensure that their after-audit tax liability remains stable (Slemrod et al. 2001). For example, a recent report by PricewaterhouseCoopers (2004, 6) stresses that: "Tax compliance risk also includes the risks arising from. . .enquiries on, or the audit of, submitted tax returns . . . by fiscal authorities . . . [T]he final agreement of a tax return often ends in a 'horse trade' between the taxpayer and the relevant revenue authority; it may make sense to have a number of aggressive positions in the return so that there is something to give as part of any negotiations." In other words, companies may undertake more aggressive positions to provide some negotiating room when they perceive that an IRS audit is more likely.

Similarly, the IRS may share this interpretation of its bargaining process with firms. Slemrod (2007, 32) recounts that: "IRS Commissioner Mark Everson (2005) testified to the President's Advisory Panel on Tax Reform that the IRS had 'a reputation for trading [penalties] away,' so that it was 'always in the interest of the noncompliant taxpayer to take an aggressive position with the Service.'" Further, if managers believe that the IRS benchmarks the firm's tax position this year to its tax position last year, then managers may surmise that deviating from avoidance strategies implemented previously may attract more intense IRS scrutiny this year.

Moreover, since corporate tax departments sometimes operate as profit centers with their directors having incentive to increase current year profits or decrease GAAP effective tax rates (Martucci 2001; Hollingsworth 2002; Robinson et al. 2010), they may be reluctant to pursue other favorable tax outcomes, such as attempting to reduce the frequency of future audits (Armstrong et al. 2012; Slemrod 2004). Adding tension to our analysis, managers may also discount the cost of an IRS audit when they consider their tax position to be highly defensible. For example, Hanlon et al. (2007) document that of the firms audited in their sample, 45 percent had no proposed tax deficiency and of those firms with a proposed deficiency identified by the IRS, only 60 percent of these amounts were later paid, suggesting that even conditional upon occurring, these audits are sometimes not very costly to firms. In short, it remains an empirical question as to whether strict IRS monitoring deters corporate tax avoidance.

To address our research question, we primarily gauge corporate tax avoidance with firms' cash effective tax rates, which is the amount of cash taxes paid by the firm scaled by its pretax income. We follow Guedhami and Pittman (2008) and Hanlon et al. (2011) by relying on data from the Transactional Records Clearinghouse (TRAC)—a nonpartisan research watchdog affiliated with Syracuse University that publicly releases statistics on the performance of many federal agencies according to the government's own real data—to measure on-the-ground IRS enforcement. This data source suits our focus on how the agency actually exercises its authority to enforce tax compliance.

Given our interest in capturing the *ex ante* threat of an IRS audit according to managers' perceptions rather than its actual incidence, we mainly specify corporate tax enforcement using a TRAC report on time-varying audit probabilities across the eight nominal asset levels that the IRS use in aggregating its auditing data.[1] We also conduct a survey of managers, which validates our primary test variable in that a substantial number of managers use historical data provided by the tax authority (which is the source of the TRAC data) to gauge tax enforcement. Our analysis spans the earliest (1992) to the latest (2008) year that IRS audit rate data are available. Analyzing this long timeframe is constructive for identification since corporate tax enforcement was ascending at some points during this period and descending at others. However, we caution that this time-series variation is imperfect for our purposes given that IRS enforcement was generally declining during the 17 years under study, with the rise in enforcement predominantly occurring within a short period late in the 1992–2008 timeframe. More positively, the source of variation in IRS audit rates that reflect firm size, time, and interactions between them—factors generally considered removed from management choice—is likely exogenous.[2]

We find that closer IRS monitoring limits corporate tax avoidance. Since IRS audit rates are aggregated by firm size and time, we triangulate our results to help dispel concern that the impact of either of these variables is spuriously behind our evidence. However, we continue to observe an inverse relation between IRS enforcement and tax avoidance when we re-specify the controls for both size and time in several ways. Economically, our coefficient estimates translate into firms' cash effective tax rates rising by, on average, almost two percentage points (a 7 percent increase in relative terms) when the probability that the firm will be subject to an IRS audit increases from 19 percent (the 25th percentile in our data) to 37 percent (the 75th percentile).

In supplementary analysis, we isolate whether the role that active IRS monitoring plays in constraining aggressive tax planning hinges on the quality of firm-level governance. This helps triangulate our main result and complements recent evidence on the interplay between governance and taxation (e.g., Desai and Dharmapala 2006). We examine whether governance characteristics—specifically, the equity stakes held by institutional investors, Gompers et al.'s (2003) index, and external auditor choice—shape the link between corporate tax enforcement and avoidance.

---

[1] These data are graphically displayed, and the asset-size categories are listed, in Panel A of Figure 1. Our specification assumes that managers form rational expectations about the probability that their firm will be audited with actual IRS audit rates representing unbiased estimates of their unobservable perceptions. Although we initially assume that any errors that managers make in predicting future IRS audit rates are unsystematic (i.e., any deviations from perfect foresight are random), we later relax this assumption by analyzing whether the impact of lagged IRS audit rates on corporate tax avoidance is sensitive to gauging expectations with historical rates. We also examine whether our core evidence holds when we measure IRS monitoring with lead audit rates to reflect that it can take the agency more than a year to finish its investigation. Data constraints force extant cross-country research to measure corporate tax enforcement with indices that are constant over time; e.g., Dyck and Zingales (2004), Haw et al. (2004), Morck and Yeung (2005), and Desai et al. (2007).

[2] However, firms can pursue corporate policies such as acquisitions, divestitures, and share repurchases that materially affect their size. None of our core results are sensitive to confronting this potential source of endogeneity with, for example, instrumental variables and panel data estimations.

Prior research implies that self-dealing managers can exploit complex tax planning, under the pretext that lowering taxes benefits shareholders, to hide their diversionary activities by suppressing information essential for monitoring (e.g., Desai and Dharmapala 2006; Graham and Tucker 2006; Desai et al. 2007). It follows that IRS monitoring will matter more when the firm's own governance structures are lax. In evidence consistent with this perspective, we find that the impact of IRS audit rates on corporate tax avoidance is larger in poorly governed firms. Collectively, our research suggests that IRS monitoring looms large in preventing corporate tax avoidance, particularly when firm-level governance is weaker.

By documenting that tougher IRS monitoring deters firms from pursuing aggressive tax strategies, we contribute to extant research by responding to calls for evidence that helps to explain corporate tax avoidance (Shackelford and Shevlin 2001; Graham 2008; Desai and Dharmapala 2010). Our analysis also provides empirical support for theory aimed at understanding the intersection between corporate tax behavior and tax enforcement (i.e., Crocker and Slemrod 2005; Shackelford et al. 2008).[3] We also complement recent evidence that the IRS plays a valuable (nontax) external monitoring role by focusing on *managers'* rather than investors' perceptions. Although it would be premature at this early stage to propose policy prescriptions, such as recommending that the government should devote more resources to corporate tax enforcement, we help fill another void by providing some insight on the tax revenue implications of IRS monitoring (Hanlon and Heitzman 2010).

The rest of this paper is organized as follows. Section II motivates the testable prediction. Section III outlines our research design. Section IV covers our empirical results. Section V concludes.

II. MOTIVATION

In this section, we outline prior research to develop the intuition that strict IRS monitoring lowers corporate tax avoidance. There is considerable theory and empirical evidence that tough IRS enforcement improves *individual* tax compliance (e.g., Allingham and Sandmo 1972; Alm et al. 1992; and Slemrod et al. 2001). However, Cowell (2004) and Kopczuk and Slemrod (2006) stress that extant empirical research on this issue for firms remains scarce.[4]

Dyreng et al. (2008) show that effective tax rates (ETRs) are a choice variable, suggesting that firms can strategically avoid taxes over the long run. Similarly, Mills (1996) and Mills et al. (1998) report that firms that spend more on tax planning enjoy lower tax burdens. At the executive level, prior research documents that annual bonuses (Hanlon et al. 2007), equity-based incentives (Desai and Dharmapala 2006), and the compensation paid to CFOs and CEOs (Rego and Wilson 2010) affect corporate tax aggressiveness. In focusing on activities within corporate tax departments, more recent evidence supports that tax director incentives lead to lower GAAP ETRs, unlike their minimal impact on firms' cash ETRs (Armstrong et al. 2011; Robinson et al. 2010). Moreover, Dyreng et al. (2010) find that individual managers' characteristics affect corporate tax planning. In contrast, we focus on the other side of the equation by providing evidence on whether the government expending more resources on enforcement constrains firms—and their managers—from aggressively reducing taxes. In short, we extend research on the determinants of corporate tax avoidance to include IRS monitoring.

---

[3] Although there is extensive evidence on individuals' responses to the severity of tax enforcement, prior research seldom examines its importance to *corporate* tax avoidance. However, there are some exceptions. Most notably, Rice (1992) relies on IRS data to provide evidence that income tax compliance is higher for public firms and firms belonging to regulated industries, and lower for firms located in tax havens. Corroborating that newly public firms experience a permanent increase in tax pressure, Pagano et al. (1998) estimate that these firms pay 2 percent more in taxes the year after their initial public offering, which they attribute to the resulting greater accounting transparency and closer scrutiny from tax authorities constraining firms from eluding taxes.

[4] While prior research supports that rigorous IRS monitoring improves individual tax compliance, this evidence does not necessarily imply that a similar link prevails between IRS enforcement and the firm. Although Slemrod et al. (2001) find that individuals pay more in taxes when they face higher audit probabilities, this result does not hold for their subsample of wealthy individuals, who actually decrease their level of tax compliance given a high probability of audit. Since sophisticated firms may behave more like wealthy individuals than like the average individual, the general finding of a positive relation between tax compliance and IRS auditing may not extend to firms. Accordingly, analyzing firm reactions to variations in IRS monitoring is important in its own right.

In analyzing confidential corporate tax returns, Mills and Sansing (2000) find that the probability that the government will audit a transaction is higher for firms that generate book-tax differences. Prior research (e.g., Mills 1998) and federal government publications (e.g., U.S. Department of the Treasury 1999) suggest that firms can deflect IRS attention by narrowing the gap between their financial reporting and taxable incomes. IRS guidelines specifically instruct their agents to investigate when book income seriously diverges from taxable income, reinforcing both tax advisors' (Cloyd 1995) and corporate managers' (Cloyd et al. 1996) perceptions that conformity leads to lower tax audit costs.

Relevant to our research question, there is some indirect evidence that the threat of IRS monitoring affects firms' financial reporting decisions. In closely dissecting 27 firms sanctioned by the SEC for inflating earnings that were eventually restated, Erickson et al. (2004) estimate that these firms resorted to deliberately overpaying their taxes by 11 cents, on average, to legitimize each dollar of fraudulently exaggerated earnings. Similarly, in large-sample analysis, Lennox et al. (2010) find evidence that the likelihood that firms perpetrate accounting fraud is decreasing in their tax avoidance. Erickson et al. (2004, 388) explain that their results might reflect that managers committing accounting fraud "may willingly have their firms pay taxes on the earnings overstatements to avoid raising the suspicion of savvy investors, the Securities and Exchange Commission (SEC), or the Internal Revenue Service (IRS)."

However, there is evidence running in the opposite direction that casts doubt on the role that the IRS plays in external monitoring. For example, it is somewhat hard to accept that the IRS operates as an information intermediary in the capital markets when it did not identify any of the accounting frauds under study in Erickson et al. (2004), which is consistent with Dyck et al.'s (2010) evidence from a more comprehensive sample. Moreover, Phillips et al. (2003) and Frank et al. (2009) find that financial reporting aggressiveness tends to accompany tax aggressiveness, implying that firms concurrently manage book income upward and taxable income downward. The mixed prior evidence on the impact of tax enforcement on the corporate financial reporting process helps to motivate our analysis on whether firms exploit lax IRS oversight to aggressively lower their taxes.

Firms weigh the marginal benefits and costs stemming from their tax-planning strategies to ensure that they remain optimally aggressive (Scholes et al. 2008). We contribute to extant research by analyzing whether firms consider the severity of IRS monitoring when choosing their level of tax avoidance. An IRS audit can potentially impose nontrivial costs in the form of proposed audit adjustments, fines, penalties, and interest. For example, IRS audit adjustments levied on firms with assets exceeding $250 million (which represent a majority of our sample) totaled $17.9 billion in 2007, indicating that the average large firm had $25.7 million in proposed IRS audit adjustments in that year (IRS 2007). Wilson (2009) estimates that firms had median savings of $66.5 million from their tax shelters, an amount almost eclipsed by the $58 million in interest and penalties that the IRS assessed on these tax shelter deficiencies. It follows that firms should rationally consider IRS audit coverage rates when developing their tax avoidance position evident in their effective tax rates, which capture variation in corporate tax aggressiveness (Armstrong et al. 2012; Dyreng et al. 2010; Robinson et al. 2010).

However, a necessary condition to support that firms weigh IRS monitoring in selecting their tax avoidance level is their familiarity with the agency's enforcement practices. Firms can obtain information about IRS coverage rates in various ways: (1) through budget reports that indicate shifts in IRS funding; (2) news about structural changes in the IRS; (3) hiring former IRS employees; (4) leadership changes at the IRS; (5) changes in financial accounting standards; (6) trends in government revenue; (7) maintaining contact with former employees who currently work at the IRS; (8) formal and informal meetings with IRS officials and employees; (9) talking with peer firms undergoing audits; and (10) accessing historical annual and monthly audit coverage data released by the IRS or organizations that monitor the IRS.[5]

The tax avoidance strategies that firms adopt will likely reflect their understanding of trends in IRS enforcement activities. By optimizing their tax strategy to avoid enforcement actions, firms can lower the costs associated with fines, penalties, and interest that they may incur if caught under-reporting. Additionally, firms can avoid the negative publicity and costly litigation that may ensue from an IRS audit. We examine whether firms experiencing tighter IRS enforcement practice less tax avoidance to enable them to reduce both their probability of getting selected for audit and the costs of that audit if it does occur.

Although it may appear intuitive at first glance that strict IRS monitoring constrains corporate tax avoidance, there are several arguments that call into question whether we will observe this relation. Apart from the reasons already outlined, firms may hesitate to pursue aggressive tax strategies—regardless of the level of enforcement that the IRS imposes—when they are sensitive to the negative publicity that this may attract. Hanlon and Slemrod (2009) explain that firms may deliberately reduce their tax avoidance in order to avoid suffering the political costs that can come with being labeled tax aggressive. For example, Citizens for Tax Justice released a series of high-profile studies demonstrating that many large, profitable U.S. firms pay hardly any taxes. Similarly, Mills et al. (2010) find evidence implying that political costs constrain tax aggressiveness evident in federal contractors limiting their tax avoidance behavior.

We surveyed members of the Tax Executive Institute (TEI) for their insights on the link between corporate tax enforcement and avoidance. We administered this survey (see Appendix A) as a supplement to an ongoing survey by TEI of its membership working for firms with multinational operations and received responses from 50 tax directors (these questions were added near the end of the survey period).[6] Participants were asked, "From your experience, does a company's assessment of a higher probability of tax authority audit lead the company to..." The majority of respondents (59.1 percent) replied "take a less aggressive tax position due to the risk of being challenged," which is consistent with our prediction. However, the rest (40.9 percent) replied that it would either "have no effect on the tax position taken," or "take a more aggressive tax position for expected bargaining purposes." In short, although our sample is small, a large fraction of respondents indicate that their companies do not become less tax aggressive when enforcement is stricter. This reinforces the view that considerable uncertainty surrounds whether corporate tax avoidance varies systematically with IRS monitoring.

---

[5] (1) The IRS's proposed and final budgets are matters of public record. As an example, the IRS once commented on the importance of financial resources: "The main reason for the large decline in these closures [tax return audit closures] is the overall drop in examination resources" (Internal Revenue Service 2003). (2) For example, the establishment of the Large and Medium Sized Business (LMSB) division of the IRS or the passage of the Internal Revenue Service Restructuring and Reform Act of 1998 affected IRS corporate audits. (3) In one example, PricewaterhouseCoopers (PwC) issued a press release in 2006 announcing the appointment of a new managing director in their Washington National Tax Service, a 35-year veteran of the IRS's LMSB division (PwC 2006). (4) Mark Everson replacing Charles Rossotti as IRS Commissioner in May 2003 precipitated a major shift in the vision of enforcement at the IRS. "Almost from the first day of Everson's five-year term, his official statements have reflected the belief that tougher enforcement was required to recover the 'many billions of dollars of lost tax revenues'" (TRAC 2005). (5) Blouin et al. (2010, 2–3) highlight that "On May 9, 2007, KPMG surveyed approximately 4,000 webcast participants with the question 'Is FIN 48 likely to increase audits by tax enforcers?' Eighty-nine percent thought it was at least likely." (6) IRS audits are often assumed to increase as government revenues fall; e.g., Associated Press (2009). (7) For example, a former tax director of a *Fortune* 100 firm and former President of the Tax Executives Institute (TEI) was made the director of the IRS's LMSB division (TEI 2003). (8) In the minutes of a formal meeting between the IRS LMSB division and the TEI, it was asserted that communication between the IRS and TEI happens not only through formal meetings, but also through "the many informal contacts with TEI officers and staff and LMSB officials' participation in chapter, regional, and Institute meetings" (TEI 2007). (9) Entities such as the Tax Executives Institute and the Manufacturers Alliance for Productivity and Innovation facilitate such exchanges. (10) The IRS was ordered by the court to release audit coverage data on a monthly basis (*Sue B. Long v. United States IRS*, April 4, 2003).

Further, public enforcement agencies are known to have limited information on both general and firm-specific conditions as well as auditing resources (e.g., Roe and Jackman 2009). Indeed, Hanlon and Heitzman (2010, 12) stress that "It is somewhat hard to believe that financial markets perceive the IRS as competent enough to monitor given the plethora of stories about how the agency has few resources and little talent to match that of corporate tax departments." After merging formerly undisclosed IRS operational audits and appeals data with confidential corporate tax return data, Hanlon et al. (2007) document that the largest firms in their sample with assets exceeding $5 billion had the highest tax deficiency rate at 74 percent. In other words, large firms subject to closer IRS monitoring exhibit more tax noncompliance, implying that IRS scrutiny may be less important. Since institutional realities call into question whether lower corporate tax avoidance accompanies stricter tax enforcement, our analysis helps to empirically resolve whether firms subject to tighter IRS oversight react by undertaking less aggressive tax positions. Consequently, we examine the prediction (stated in the alternative) that corporate tax avoidance subsides when the IRS imposes tougher monitoring:

H1: Firms' tax avoidance, *ceteris paribus*, will decrease with the probability of an IRS audit.

III. RESEARCH DESIGN

Regression Equation

We test our prediction that corporate tax avoidance falls with stricter IRS monitoring by estimating several versions of the following model using ordinary least squares (we suppress subscripts for simplicity):

$$CASH\ ETR = \beta_0 + \beta_1 AUDIT\ PROBABILITY + \acute{\beta}_2 X + \beta_3 INDUSTRY + \beta_4 YEAR + v. \qquad (1)$$

The dependent variable, *CASH ETR*, is cash taxes paid divided by pretax book income after removing the effects of special items (Dyreng et al. 2010). This measure reflects both permanent and temporary book-tax differences, and avoids overstating the current tax expense that arises from the tax benefits on employee stock options. We follow recent research by constraining *CASH ETR* to range between 0 and 1 (Chen et al. 2010; Lisowsky et al. 2011; Dyreng et al. 2008). Since we require all firms to have positive pretax income, any negative values for *CASH ETR* occur when the firm has negative tax expense (presumably a refund).[7]

---

[6] Our survey results may suffer from a nonresponse bias. This is especially important because our participants came only from respondents who replied after a second notice from TEI. Using Wallace and Mellor's (1988) method, we detect no major statistical difference in the characteristics of the respondent firms in terms of size, industry, or geography relative to the earlier responders. In a second test, we find that our sample of firms is generally comparable in size and industry to the general population of TEI member firms, except that we have a higher concentration of manufacturing firms. Although we could not identify any obvious bias stemming from this difference, we cannot dismiss that nonresponse bias of unknown severity may afflict our results.

Extant research differs concerning the proper aggregation length of cash ETRs. While Dyreng et al. (2008) suggest that aggregating the measure over several years smoothes transient shocks to the measure, Dyreng et al. (2010) use a one-year measure of *CASH ETR*. We asked TEI survey respondents how long different tax-planning positions/transactions would take to be adjusted if there was a change in assessed tax risk. Survey participants responded that 12 percent of tax positions could be changed within a month, 39.6 percent within six months, 69.2 percent within one year, 91.25 percent within two-to-three years, and 100 percent within three-to-five years, helping to justify using a one-year *CASH ETR* in our setting. However, we later consider whether our core evidence on the prediction in H1 is sensitive to quantifying corporate tax avoidance with a three-year cash ETR.

We rely on a TRAC (2009) report to specify our primary test variable, *AUDIT PROBABILITY*, which proxies for the likelihood that the firm will be subject to an IRS audit. Specifically, we code *AUDIT PROBABILITY* as the number of corporate tax return audits completed in the IRS's fiscal year *t* for an IRS asset size group a, divided by the number of corporate tax returns received in the previous calendar year for the same IRS asset size group a.[8] *AUDIT PROBABILITY* (its numerator) is graphed in Figure 1, Panel A (Panel B). To justify that *AUDIT PROBABILITY* reflects managers' unobservable perceptions, we appeal to rational expectations by assuming that actual IRS audit rates amount to unbiased estimates of their expectations.

In order to obtain some insight to validate whether firms follow IRS monitoring trends, we surveyed members of the Tax Executive Institute (Appendix A). Seventy-two percent of respondents suggested that they assess audit probabilities when making corporate tax decisions. Given that firms apparently track IRS enforcement activities, we next consider the empirical relevance of our proxy for the agency's monitoring. Of survey participants, 93.1 percent reported relying on discussions with a tax advisor to gauge the audit likelihood. Other popular information sources according to the survey were "discussions with peer institutions" (51.7 percent), "discussions with an auditor" (37.9 percent), and "past audit rates disclosed by the tax authority"

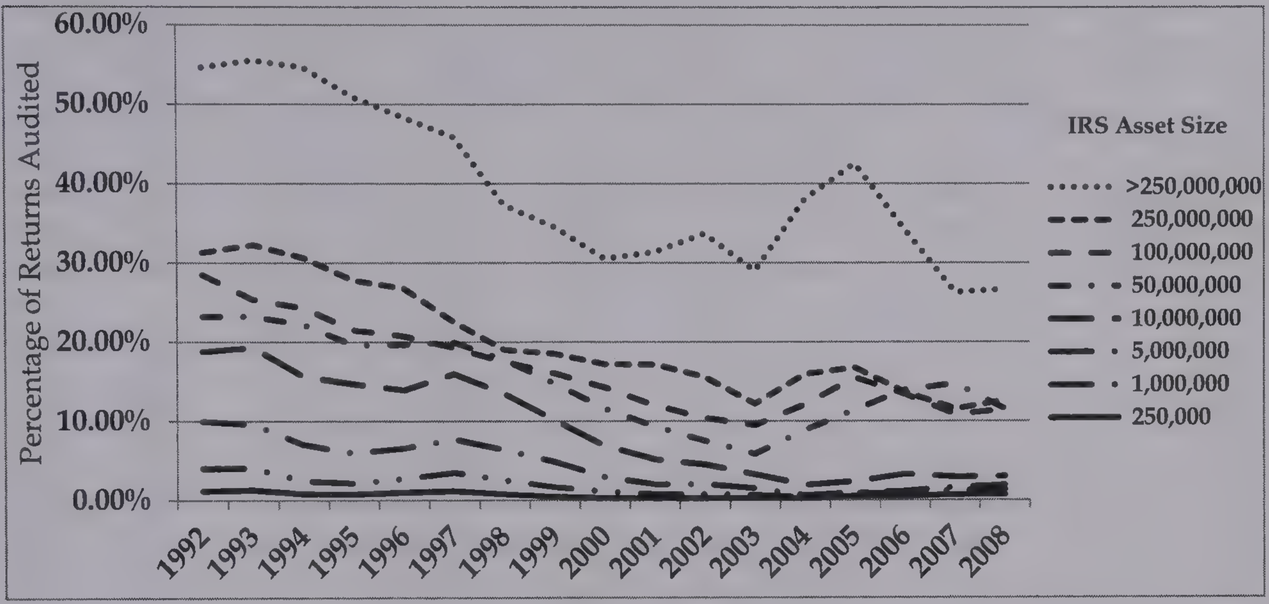
---

[7] There are multiple measures of tax avoidance/evasion, all of which capture some component of the tax avoidance spectrum (Hanlon and Heitzman 2010; Lisowsky et al. 2011). We primarily focus on a one-year *CASH ETR* in the analysis because it is a broad measure of tax avoidance. We do not have strong priors about which section of the tax avoidance spectrum stricter IRS tax enforcement will affect, and certain other measures are inappropriate for our research question. Book-tax differences (BTDs), for example, assume that book income is not affected by our variable of interest, which seems difficult to justify in our setting (Hanlon et al. 2011). Using BTDs assumes that firms practice nonconforming tax avoidance. Besides since firms participating in tax shelters tend to exhibit large BTDs (Wilson 2009), extensive evidence implies that these amounts reflect earnings management activities and general business conditions; e.g., Mills and Newberry (2001), Philips et al. (2003), Lev and Nissim (2004), and Hanlon (2005). Second, many papers rely on predictive models of tax shelters to identify aggressive tax behavior, especially as measured by the Lisowsky (2010) and Wilson (2009) models. These models are inappropriate for our research question given that they construct the model using tax shelters (listed transactions) that were caught by the IRS (disclosed to the IRS). We do not expect firms to vary the number or type of transactions that they specifically disclose to the IRS in fear of those transactions being audited by the IRS. However, a limitation inherent in gauging tax avoidance with ETRs is that this necessitates excluding firms with negative pretax income, meaning that we cannot generalize our inferences to unprofitable firms. Further, since the TRAC statistics on audit coverage are aggregated across all firms, including those incurring losses, this sample restriction injects noise that almost certainly works against our tests rejecting our null hypothesis.

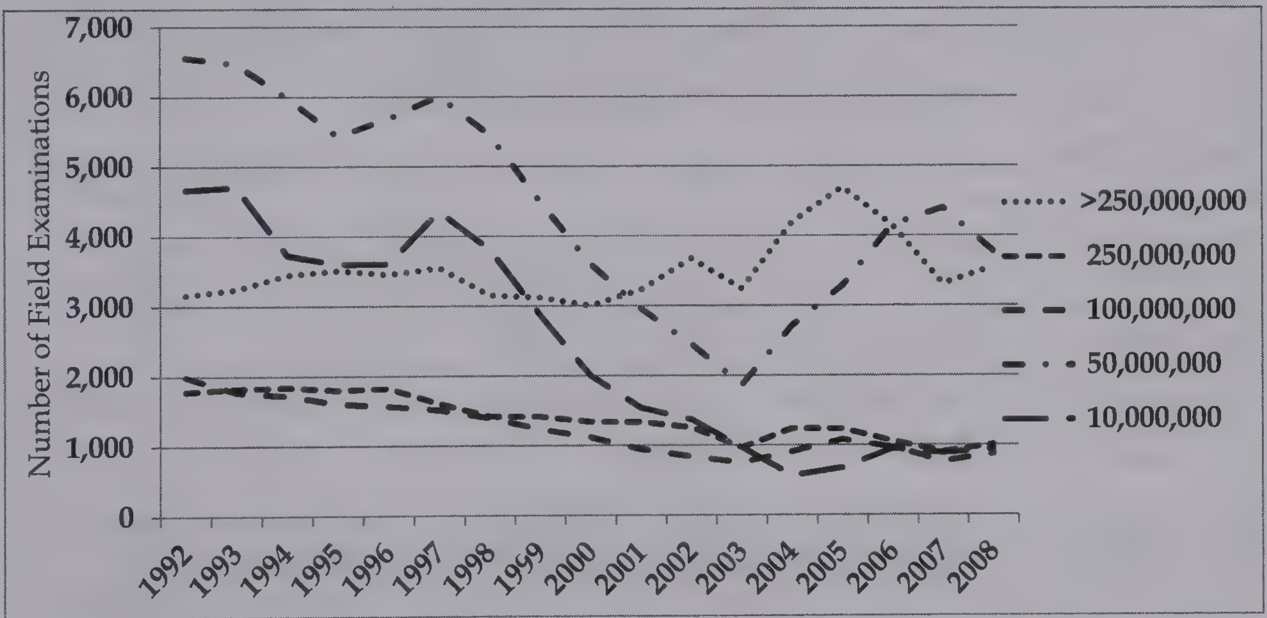
[8] While *AUDIT PROBABILITY* varies only by time and size, this is a function of the IRS aggregating the way they report audit coverage statistics, rather than as a result of the underlying process that determines which firms get audited. The true selection process for IRS audits, which is unknown to managers (and researchers), likely contains firm size as only one of several parameters. These data are an aggregation of data the IRS discloses in its annual Databook, which has been posted to the website of the IRS's Statistics of Income Division.

FIGURE 1
IRS Audit Coverage

Panel A: IRS Audit Coverage for Corporations, by Asset Size, 1992–2008



Panel B: Number of Corporate Audits Completed in IRS Fiscal Year, by Asset Size, 1992–2008



These graphs display the audit probability (Panel A) and the numerator (Panel B) of audit probability, for firms in specific IRS asset classes using data obtained from the Transactional Records Access Clearinghouse. In Panel A, each line represents the proportion of corporate tax audits completed in the given IRS fiscal year *t* for that asset class, divided by the number of corporate tax returns in IRS calendar year *t*–1 for that asset class. In Panel B, the lines represent the number of face-to-face IRS audits conducted each year in each IRS asset size pool. Panel B excludes asset sizes below $10,000,000 in assets, as including them makes the variance in the larger (and more relevant) asset size class groups almost indiscernible.

TABLE 1

Sample Selection

Panel A: Number of Observations for Each IRS Asset Level from Compustat Sample

Year	Less than $250,000	$250,000–$1 Million	$1–$5 Million	$5–$10 Million	$10–$50 Million	$50–$100 Million	$100–$250 Million	$250 Million or More	Total
1992	5	24	148	199	840	507	593	1449	3765
1993	5	14	146	182	895	541	675	1558	4016

Panel B: Number of Observations Surviving Each Sample Screen

Sample Selection	Firm-Year Observations
Firms with data on assets	173,231
Firms incorporated in the U.S.	143,151
Firms located in a U.S. state	140,489
Firms with positive net income less special items	87,961
Firms with the data required for all control variables	66,310

This table reports the distribution of the sample by calendar year and asset level in Panel A and the screening process applied to assemble the sample in Panel B.

(31 percent). These results suggest that nearly a third of firms rely on historical rates, which is the construct that our primary test variable, *AUDIT PROBABILITY*, is intended to measure.[9]

Table 1, Panel A shows the number of observations in each IRS asset level/year cell, and indicates that the share of sample observations rises almost monotonically with firm size, with very large firms with assets exceeding $250 million, comprising nearly 55 percent of the sample. The observations are fairly evenly spread over time. Importantly, the variation across asset level and over time reinforces that our tests have adequate power to gauge the impact of IRS audit rates on deterring firms from aggressively avoiding taxes, even when we estimate saturated regressions that control for year and firm size with dummy variables. Our identification strategy benefits from *AUDIT PROBABILITY* likely being exogenous since it stems from asset level, year, and their interaction.

---

[9] Moreover, the 31 percent frequency may be a lower bound estimate given that firms may indirectly rely on historical audit rates to evaluate tax enforcement severity since insights shared by their tax advisors, external auditors, and peer institutions may be partly based on perceptions of such rates.

The limitations of calibrating IRS monitoring with *AUDIT PROBABILITY* include the fact that this approach assumes that corporate audits are completed in one year. The IRS (2008, 25) supports this assumption by asserting that "In general, examination activity is associated with returns filed in the previous calendar year." We note that audits are closed (and included in *AUDIT PROBABILITY*) when the examination is completed and audit adjustments are proposed, not when the case is finally closed with settlement or the end of litigation. Second, *AUDIT PROBABILTY*'s aggregation using asset size groups treats the probability of audit as a step function of only asset size, while it is most likely a relatively smooth function defined over many different factors. This likely underestimates (overestimates) the probability of audit for firms on the upper (lower) bound of an asset size group. Both of these problems are minimized to the extent that managers are using TRAC-like data to estimate audit probability for their firms.[10] We therefore seek to rigorously control for the role of firm size and time in the analysis since these characteristics dictate *AUDIT PROBABILITY*.

In Equation (1), X stands for a vector of firm-specific controls for size, leverage, capital expenditures, research and development costs, profitability, the presence of, and changes in, tax loss carryforwards, foreign income, and the presence of a Big 4 auditor. The choice and specification of these control variables, which we define in Appendix B, closely resembles recent research on the determinants of corporate tax avoidance (e.g., Dyreng at al. 2008, 2010; Wilson 2009; Chen et al. 2010).[11] We include dummy variables representing the Fama and French (1997) 48 industries given evidence that cash ETRs vary systematically across industries (Dyreng et al. 2008). Besides controlling for changing macroeconomic conditions and tax laws, we include year fixed effects in most estimations since our primary test variable, *AUDIT PROBABILITY*, partly depends on time. In sensitivity analysis, we also explore specifications that impose a linear trend on corporate tax avoidance over time with a variable, *TREND*, that has the value 1 for 1992, 2 for 1993, etc.

Sample Formation

We begin with the 173,231 firm-year observations available on Compustat for 1992–2008, the longest period with IRS audit rate data available from TRAC. We restrict our sample to U.S. incorporated firms (leaving 143,151 observations) that are headquartered in a U.S. state (140,489 observations). Next, the requirement for firms to have positive pretax income before special items reduces the sample to 87,961 observations.[12] Finally, we eliminate firm-years without the data necessary to calculate the control variables, leaving an unbalanced panel consisting of 66,310 observations for 10,626 unique firms. We summarize our sample selection process in Panel B of Table 1.

---

[10] Further, all of these limitations suggest that researchers considering using *AUDIT PROBABILTY* need to weigh the limitations of the proxy against the benefit to answering an important research question. Given that our question lies at the heart of firm tax planning and governmental tax enforcement, we believe that relying on this proxy is justified in our setting despite its inherent shortcomings.

[11] Including endogenous right-hand-side variables as controls for factors that affect the budget set for the firm is common practice in accounting research, although it does raise some interpretational concerns. We control for factors that affect the ability or incentives of firms to practice tax avoidance and interpret the coefficient on *AUDIT PROBABILITY* as the impact that the IRS's actions have on corporate tax avoidance. We re-estimate our baseline regression without the firm-specific controls (i.e., containing only industry and year dummy variables) and still find strong support for the prediction in H1 that stricter IRS enforcement is associated with decreased corporate tax avoidance. Moreover, the fact that our evidence persists alleviates concern that our analysis suffers from an omitted variable problem.

[12] We follow extensive prior research by removing loss firms because of the difficulty of interpreting their ETRs, which naturally restricts the generalizability of our inferences to strictly profitable firms. This likely also makes the distribution of *AUDIT PROBABILITY* in our sample different than the universe of U.S. corporations since the probability of suffering a loss likely hinges on firm size (Mills 1998).

Descriptive Statistics

We present descriptive statistics for firms in our sample in Panel A of Table 2, which include that the mean (median) *CASH ETR* at 27 (25) percent is similar to recent research. Panels B and C of Table 2 show that the Pearson pair-wise correlation coefficient between *CASH ETR* and *AUDIT PROBABILITY* is positive and statistically significant at the 1 percent level, and this evidence persists for the alternative ETR proxies listed in this table. As discussed later, the four ETR proxies exhibit positive correlations with each other, but some of these correlations are relatively small, which is likely to reflect these variables capturing different facets of firms' tax avoidance activities, as well as measurement error. These correlations reinforce the importance of triangulating our analysis by specifying different ETR proxies in the regressions.

IV. EMPIRICAL RESULTS

Evidence on the Prediction in H1

In Table 3, we report evidence on the role that IRS monitoring plays in corporate tax avoidance according to Equation (1). In these linear regressions, our inferences reflect standard errors clustered by firm (as a time-dependent variance component will be partially captured by the year fixed effects).[13] The controls vary systematically in the expected directions in our baseline regression in Column (1), except for *FOREIGN INCOME*.[14] More relevant for our purposes, *AUDIT PROBABILITY* loads positively at the 1 percent level, which is consistent with the prediction in H1 since *CASH ETR* is an inverse measure of corporate tax avoidance. Economically, the coefficient estimate of 0.104 implies that firms' cash effective tax rates rise, on average, by 7.3 percent, from 25.5 percent to 27.4 percent, when the likelihood that the firm will be subject to an IRS audit increases from 19 percent (the 25th percentile in our sample) to 37 percent (the 75th percentile). Given our sample average cash taxes paid of $44.1 million, this 7.3 percent increase in *CASH ETR*s would equate to an increase in cash taxes paid by the average firm in our sample of $3.2 million, reinforcing that the impact is economically material.

In the next six regressions, we control for firm size and time in several other ways because these characteristics determine *AUDIT PROBABILITY*. The Column (2) results use nine dummy variables representing the asset deciles to provide the data more flexibility. In this more saturated model that also includes calendar year and industry dummies, we still find that *AUDIT PROBABILITY* loads highly positively in a two-tailed test. Similarly, the evidence supporting the prediction in H1 that firms are less tax aggressive when IRS monitoring is stricter persists when we

---

[13] We only cluster at the firm level because the regressions include year fixed effects. Petersen (2009) stresses that cluster size needs to be sufficient to ensure viable estimates using clustered standard errors. It might be difficult to accept that our relatively short timeframe is sufficient to obtain the large-sample properties necessary to justify clustering by year. However, in an untabulated robustness test, we still find that *AUDIT PROBABILITY* loads positively at the 1 percent level when we cluster by both year and firm, consistent with the prediction in H1.

[14] Although controlling for capital expenditures reduces concern that fluctuations in bonus depreciation is spuriously responsible for our results, we continue to find supportive evidence when we re-estimate this regression after discarding observations exceeding the 90th percentile in this variable's distribution.

This table presents distributional statistics and Pearson correlation coefficients between the regression variables for the 66,310 firm-year observations used in the hypotheses tests. Panel A includes the mean, standard deviation, first quartile, median, and third quartile. Panel B reports the Pearson pair-wise correlations in bold indicating statistical significance at the 1 percent level. *AUDIT PROBABILITY* is the number of face-to-face corporate audits completed in IRS fiscal year *t* in a given IRS asset size divided by total number of 1120 returns filed in calendar year *t*−1, in an IRS asset size. *CASH ETR* is cash taxes paid scaled by pretax income. *NON-CONFORMING CASH ETR* is the cash taxes paid scaled by cash flows from operations. The *3-YEAR CASH ETR* is the sum of year *t* through year *t*+*2*'s cash taxes paid scaled by the sum of pretax income over the same time period. *GAAP ETR* is the total income tax expense scaled by pretax income. *DISTRICT/SIZE/TIME AUDIT PROBABILITY* is the number of corporate tax audits completed in IRS fiscal year *t* in a given IRS district for a given IRS asset class group, divided by the number of corporate tax returns received in that same district and IRS asset size group in IRS calendar year *t*−1. *DISTRICT/TIME AUDIT PROBABILITY* is the number of corporate tax audits completed in IRS fiscal year *t* in a given IRS district, divided by the number of corporate tax returns received in that same district in IRS calendar year *t*−1. *Log*(*ASSETS*) is the natural log value of total firm assets. *Log*(*SALES*) is the natural log value of total sales. *Log*(*MVE*) is the natural log value of the market value of equity of the firm. *LEVERAGE* is the total long-term debt scaled by lagged assets. *INVENTORY INTENSITY* is the total inventory scaled by lagged assets. *R&D INTENSITY* is the research and development expense scaled by lagged assets. *CAPITAL EXPENDITURES* is the capital expenditures of the firm, scaled by lagged assets. *ROA* is the pretax income divided by assets. *NOL* is an indicator variable coded 1 if firm has a tax loss carryforward in the prior year, 0 otherwise. *ΔNOL* is the difference between year *t* and year *t*−1's tax loss carryforward, scaled by lagged assets. *FOREIGN INCOME* is the foreign income of the firm scaled by lagged assets. *BIG FOUR* reflects whether the firm appoints a Big 4 auditor in year *t*.

re-specify firm size with the natural logarithms of total sales and the market value of equity in Columns (3) and (4), respectively.[15]

Next, we apply two techniques to address the competing explanation that we are spuriously documenting that *CASH ETR* and *AUDIT PROBABILITY* are both decreasing during our sample period. Although including year fixed effects constrains our estimation to only within-year variance, using a linear trend and Fama-MacBeth regressions helps empirically clarify whether our evidence on the prediction in H1 merely stems from a trend. This examination is especially important given

---

[15] Controlling for firm size is necessary given prior research that documents the link between ETRs and firm size and, more importantly, the fact that *AUDIT PROBABILITY* is a function of asset size. However, given that the OLS estimate for the coefficient on *AUDIT PROBABILITY* in the presence of controlling for size will reflect the portion of *AUDIT PROBABILITY* that is not explained by our size control, it begs the question of what is being estimated. First, *AUDIT PROBABILITY* is a step function of asset size, so that as we linearly or log-linearly control for asset size, we are identifying off the difference in functional forms. Further, as we use several alternative size controls in separate regressions, we are also able to identify not only off the differences from the step function to the log-linear control, but also the difference in sales, market equity, or assets. In addition, we estimate (untabulated) the regression in Column (1) of Table 3 without a firm size control, and continue to find empirical support at the 1 percent level for the prediction in H1. Later, we analyze whether our evidence is sensitive to replacing *AUDIT PROBABILITY* with a test variable that does not vary according to firm size.

*, **, *** Denote two-tailed statistical significance at the 10 percent, 5 percent, and 1 percent levels, respectively.

This table presents estimation results from regressing firms' cash effective tax rates on IRS audit rates and controls. Unreported industry controls are based on the Fama and French (1997) industry classification. Beneath each coefficient estimate is reported the t-statistic based on robust standard errors adjusted for clustering by firm. Asset Deciles are indicator variables (unreported) representing the deciles in assets. *TREND* is a linear trend variable, with 1992 equal to 1, 1993 equal to 2, and so on. $TREND^2$ is the linear trend variable, squared.

All other variables are defined in the notes to Table 2, and in Appendix B.

the clearly decreasing trend in audit coverage that is visible in Panel A of Figure 1. Indeed, the probability of audit for the largest firms (asset sizes exceeding $250 million) has declined in the majority of years in our sample (65 percent), with 1993, 2001, 2002, 2004, 2005, and 2007 the only exceptions. Further, the average *CASH ETR* for firms in our sample has fallen in every year except 1995, 1997, 1998, 2004, 2005, 2006, 2007, and 2008. Collectively, this makes the time-size trend in both tax avoidance and audit coverage a largely monotonic decrease, motivating our analysis of this issue.

First, we replace the year dummies with a time trend variable (*TREND*) in the regressions in Columns (5) and (6). Although *TREND* loads negatively at the 1 percent level in Column (5), which excludes *AUDIT PROBABILITY*, when we include *AUDIT PROBABILITY* in Column (6), its negative relation with tax avoidance persists (t-statistic = 5.31). The coefficient magnitude for *TREND* in this regression falls by half—from −0.002 in Model (5) to −0.001 in Model (6). In other words, the descent in corporate tax enforcement between 1992 and 2008 partly explains the concurrent increase in tax avoidance during this period. Additionally, after including a *TREND*-squared variable in Model (7) to investigate the role that nonlinear time trends play, we continue to find that *AUDIT PROBABILITY* loads positively at the 1 percent level. We also apply the Fama-MacBeth estimation technique (untabulated), which enables inference in light of time effects or time-series dependence in the data. Operationally, this involves estimating 17 annual regressions spanning 1992 to 2008 and averaging the coefficients, which also leads to evidence that tough tax enforcement reduces corporate tax avoidance. Our core evidence on the relation between IRS enforcement and corporate tax aggressiveness remains in this Fama-MacBeth analysis, reinforcing that we are not spuriously capturing a time trend.[16]

Finally, in Models (8) and (9), we exploit the panel structure of our data by estimating fixed and random effects models, respectively, to handle firm heterogeneity (rendering industry fixed effects redundant). It is plausible that firms' unobservable, time-invariant characteristics, such as their political influence or state of residence, could affect both the intensity of IRS oversight and their tax avoidance. However, for both panel estimation techniques, the coefficient on *AUDIT PROBABILITY* continues to load positively at the 1 percent level, alleviating concern that omitted firm-specific determinants are spuriously responsible for our evidence on the link between corporate tax enforcement and avoidance.[17] In summary, the evidence reported in Table 3 suggests that higher cash effective tax rates accompany tighter IRS monitoring, although in the next sections we consider whether this inference survives additional sensitivity analysis.

Alternative Tax Avoidance Metrics

In the first three columns of Table 4, Panel A, we evaluate whether the negative relation that we observe between tax avoidance and IRS audit rates in Table 3 holds when we replace *CASH ETR* with alternative proxies. Importantly, Hanlon et al. (2011) document that IRS monitoring affects the financial reporting process. Since the denominator in *CASH ETR* is pretax net income, it may be susceptible to nontax avoidance influences of IRS external monitoring, meaning that we might

---

[16] Another concern is the spike in tax enforcement in 2004 and 2005, when firms' ETRs may have been artificially high due to dividends repatriations. Our main results also hold after removing 2004 and 2005 from the analysis.

[17] A Hausman specification test rejects the null hypothesis of no correlation between the unobserved firm-specific random effects and the explanatory variables, implying that random effects estimation is biased, inconsistent, and not the proper design choice for the data. However, we also tabulate the random effects results since Griliches and Hausman (1986) stress that observing consistent estimates across alternative panel data estimation techniques supports the absence of serious errors in variables problems. Although we find consistent results with both fixed and random effects models, it follows that OLS better suits our data given the high between-firm variation in IRS audit rates relative to its within firm variation. Fixed effects may be an inefficient estimation method in such settings according to Beck (2001) and Plumper and Tröger (2007).

*, **, *** Denote two-tailed statistical significance at the 10 percent, 5 percent, and 1 percent levels, respectively.
This table presents estimation results from regressing firms' effective tax rates on IRS audit rates and controls. Unreported industry controls are based on the Fama and French (1997) industry classification. Beneath each coefficient estimate is reported the t-statistic based on robust standard errors adjusted for clustering by firm.
All variables are defined in the notes to Table 2, and in Appendix B.

inadvertently capture only a denominator effect. Moreover, *CASH ETR* only reflects nonconforming tax avoidance. If firms practice tax avoidance that simultaneously decreases cash taxes paid and pretax income, then any change in the ETR is purely a mathematical outcome (Hanlon and Heitzman 2010). In order to ensure that our results do not stem from a mechanical denominator effect and to incorporate a measure of conforming tax avoidance into our analysis, we re-estimate the baseline regression using cash flows from operations when calculating the denominator of *NON-CONFORMING CASH ETR* (Hanlon and Heitzman 2010). This variable loads positively (t-statistic = 4.44) in Model (1), providing some assurance that our earlier evidence supporting the prediction in H1 is not an artifact of accounting-based earnings management.

Although we follow Dyreng et al. (2010) by primarily gauging tax avoidance with the one-year average *CASH ETR*, we also conduct a sensitivity test using a three-year average for two reasons. First, Dyreng et al. (2008) stress that a long-run average cash ETR smoothes transient one-year shocks to cash taxes paid or pretax income, providing a more stable measure of corporate tax avoidance. Second, traditional models of tax compliance suggest that the cost to a firm of a tax audit is not only the tax and penalties imposed on underreported income in one year, but also in all years within the statute of limitations. The IRS is apt to investigate additional years when they detect under-reporting in a certain year. Consequently, a longer-term measure of tax avoidance may better suit our research questions if managers select a consistent tax strategy realizing that years are unlikely to be audited in isolation. We calculate *3-YEAR CASH ETR* as the sum of cash taxes paid in years t, $t+1$, and $t+2$, divided by pretax income less special items in years t, $t+1$, and $t+2$. Although there are several upsides to using this specification in our analysis, we pay a heavy price in terms of sample attrition. Nonetheless, we find that *3-YEAR CASH ETR* loads positively at the 5 percent level in Column (2) despite the reduction in power, supporting the intuition that IRS monitoring constrains longer run corporate tax avoidance.

We also examine whether our results are robust to traditional GAAP measures of ETR. After specifying this variable by dividing the firm's total tax expense for the year by its pretax income, we find that *GAAP ETR* loads positively at the 1 percent level in Column (3). Our results (untabulated) also hold when we specify a domestic *GAAP ETR* as the dependent variable.[18]

Alternative IRS Monitoring Measures

In Columns (4) and (5) of Table 4, Panel A, we consider whether our core evidence on the prediction in H1 is sensitive to focusing on alternative proxies for corporate tax enforcement that vary on characteristics besides strictly firm size and time. We rely on *AUDIT PROBABILITY* in our primary analysis because the underlying data cover a longer period, 1992–2008, when tax enforcement levels were intermittently rising and falling. However, in this section, we exploit that, for the shorter 1992–2000 timeframe, the IRS also compiled audit coverage statistics aggregated by IRS district, which enables us to generate another two proxies for tax enforcement that vary according to: (1) geography, firm size, and year; and (2) geography and year. Table 5 displays audit probabilities for two randomly selected IRS districts. Significant cross-sectional variation in corporate tax enforcement is evident at the district level. Importantly, this district-level variation in audit rates varies across firm size and over time, ensuring that a district-level identification strategy

---

[18] Our results also hold when using *GAAP ETR* after shortening the estimation period to 1993–2008 to reflect changes in *GAAP ETR*s arising from FAS 109 (now ASC 740-10 and 740-30). There are several problems with using *GAAP ETR*, including that firms may accrue a larger tax cushion in response to increased perceived enforcement (this is specifically forbidden under ASC 740-10), and that this measure is artificially inflated for firms with employee stock options plans (Hanlon and Shevlin 2002). Avoiding these complications is one reason we specify *CASH ETR* as our main proxy. However, to ensure that this sensitivity test is robust to adjusting for the bias created by the tax implications of stock options, we perform several tests. First, we add back the tax benefit created by stock option exercises (the sum of Compustat items txbco and txbcof) to tax expense in our computation of *GAAP ETR* (this test is limited because the disclosure of stock option tax benefits is sparse [Hanlon and Shevlin 2002]). In another specification, we control for the dollar value of options granted as reported by the firm (ExecuComp item OPTION_AWARDS_RPT_VALUE) scaled by assets, and the dollar value of option awards (ExecuComp item OPTION_AWARDS) also scaled by assets. All of these tests yield results that are almost identical to our earlier evidence, reinforcing that option usage by firms is unlikely to be behind our core results in this robustness test.

TABLE 5

Examples of Audit Probabilities for Selected Years and Asset Sizes for Two IRS Districts, and the Percentage Differences between the Two Districts

	Fiscal Year				
Return Type/Asset Class	**2000**	**1998**	**1996**	**1994**	**1992**
Percent of Returns Audited—Pennsylvania District					
< \$250,000 Assets	0.33%	0.86%	1.22%	0.89%	1.13%

\$250 Million Assets or more	28.20%	28.64%	36.47%	57.64%	90.27%
Percentage Difference Between Pennsylvania and the Rocky Mountain IRS Districts					
< \$250,000 Assets	21.21%	44.19%	43.44%	25.84%	−55.75%
\$1 Million < \$5 Million Assets	−69.81%	9.43%	45.21%	24.52%	−64.42%
\$5 Million < \$10 Million Assets	−117.76%	−3.86%	41.37%	23.59%	−21.27%
\$50 Million < \$100 Million Assets	17.75%	45.56%	33.90%	41.07%	−19.98%
\$250 Million Assets or more	−23.41%	7.49%	14.65%	−18.77%	−102.40%

These data are taken from the Transactional Records Access Clearinghouse TracFed database. They are representative examples of the Audit Probabilities in two different districts, and the percentage difference between those districts.

is powerful.[19] Accordingly, we rely on the variation in audit rates by IRS district to re-analyze the prediction in H1.

The first of our geography-based enforcement measures, *DISTRICT/SIZE/TIME AUDIT PROBABILITY*, amounts to the number of corporate tax audits completed in IRS fiscal year *t* in a given IRS district for a given IRS asset level, divided by the number of corporate tax returns received in that same district and IRS asset level group in IRS calendar year *t*–1. The second measure, *DISTRICT/TIME AUDIT PROBABILITY*, reflects the number of corporate tax audits completed in IRS fiscal year *t* in a given IRS district, divided by the number of corporate tax returns received in that same district in IRS calendar year *t*–1. This variable does not directly depend on firms' asset level, implying that observing a positive coefficient on *DISTRICT/TIME AUDIT PROBABILITY* would reinforce our earlier analysis indicating that firm size is not spuriously responsible for our core evidence. In the resulting smaller samples, we find that *DISTRICT/SIZE/*

---

[19] Although the shorter 1992–2000 interval reduces sample size, integrating geography helps us to address a specific form of potential endogeneity. Prior research (e.g., Loughran and Schultz 2005; Loughran 2007, 2008) argues that corporate location decisions are exogenous since they are driven by proximity to customers, suppliers, and production inputs rather than, in our case, firms' attempts to lower IRS monitoring. Corroborating prior research (e.g., Hilary and Hui 2009; Pirinsky and Wang 2010; El Ghoul et al. 2012), we find that the firms in our sample seldom relocate. We verify in an untabulated regression that our inference on the prediction in H1 using location-based proxies holds when we remove from the analysis the 647 firms (4,430 observations) that moved their business headquarters anytime between 1995 and 2008 (the timeframe for which we can compile time-varying location data from regulatory filings with the SEC).

TIME AUDIT PROBABILITY and *DISTRICT/TIME AUDIT PROBABILITY* load positively at the 1 and 5 percent levels in Columns (4) and (5), respectively.

Another concern is that the largest firms in our sample almost certainly belong to the IRS's Coordinated Industry Case (CIC) program, which routinely subjects them to constant audit (Hanlon et al. 2007). In sharp contrast, our primary test variable assigns the largest firms in our sample with assets exceeding $250 million IRS audit rates that range from 26.29 percent for 2007 to 55.52 percent for 1993. However, it is difficult to reliably identify CIC firms. Gleason and Mills (2002), citing a 1995 IRS publication, suggest that the CIC program includes more than 1,000 firms each year, while Hanlon et al. (2007) estimate that the actual number is closer to 1,200 firms annually. Complicating matters, these estimates of the number of firms in the CIC program include private firms for which data constraints prevent us from including in our analysis. Moreover, inspecting mandatory SEC filings for our entire 1992–2008 study period confirms that firms seldom publicly divulge when they belong to the CIC program; i.e., we could locate fewer than 10 cases of such disclosures.

To tackle the issue that our results may be driven by the large firms in the CIC program, we follow Gleason and Mills (2011) and El Ghoul et al. (2011) by isolating whether our evidence on the prediction in H1 holds when we exclude likely CIC firms.[20] Given Hanlon et al.'s (2007) evidence that 94.1 percent of CIC firms have greater than $250 million in assets, we discard all firms that fall into this category. More generally, focusing on the firms with under $250 million in assets, which comprise 45.1 percent of our sample, is also constructive for ensuring that our results reflect pervasive economic phenomena rather than large firms dominating the analysis. Although our sample shrinks materially from 66,310 to 29,914 observations, the coefficient on *AUDIT PROBABILITY* remains positive and highly statistically significant in Table 4, Panel B, Column (6), helping to justify dismissing the presence of large CIC firms as a competing explanation.

We have outlined several limitations of the TRAC data for examining our research question. Although relying on this data source involves several shortcomings, it is publicly available and readily accessible to both researchers and managers alike. While there is a paucity of other data on the incidence of IRS audits, another potential source does exist in the form of the disclosure of such audits by the firms themselves in their public regulatory filings. It should be noted that using this as a method for documenting IRS audits brings some severe problems. Gleason and Mills (2002) find that many firms fail to disclose when they are subject to an IRS audit—even when the amounts under investigation are material for financial reporting purposes—suggesting that disclosure is a choice variable. Additionally, the nature of the data-collection process injects substantial noise into the empirical measure.[21]

To examine our research question using disclosed audit data from regulatory filings, we assemble a sample of all observations that have a 10-K, 8-K, or 10-Q in the EDGAR database. We code an indicator variable, *DISCLOSED IRS AUDIT*, 1 for all firm-years that mention the words "IRS" or "Internal Revenue Service" within ten words of the words "examination," "audit," or "investigation" in their filings. Electronic regulatory filings are only available since 1994, materially shrinking our sample size. We then average this indicator variable over IRS asset size groups and years to specify a variable analogous to *AUDIT PROBABILITY*, which we label *DISCLOSED AUDIT PROBABILITY*. We implement this averaging independent of our sample, so this measure reflects the disclosures of all public firms with available 10-Ks, 8-Ks, and 10-Qs for which we have information on asset size. Using *DISCLOSED IRS AUDIT* as a proxy assumes that managers have perfect foresight on audit likelihood (or at least of disclosing being audited), and plan accordingly. Alternatively, *DISCLOSED AUDIT PROBABILITY* would be appropriate if managers develop their expectations about the IRS audit coverage from conversations with firms of equal size (as our survey evidence suggests is the case).

---

[20] Although the IRS explains how CIC membership is determined in the Internal Revenue Manual 4.46.2, data restrictions and differences in consolidation rules prevent us from precisely identifying CIC firms.

[21] Computer programs can successfully detect the mention of phrases related to an IRS audit in a specific 10-K, although mapping this into firm-years is difficult. First, firms disclose audits of prior years. Further, some firms mention that they are not under audit, and the variation in ways they do this makes it difficult for a computer program to reliably eliminate these firms. For example, a December 31, 2009 8-K of Inergy Holdings states "No Company Benefit Plan is under audit or is the subject of an investigation by the IRS."

In a pair of untabulated regressions, we re-estimate Model 1 (Column 1 in Table 3) using *DISCLOSED IRS AUDIT* and *DISCLOSED AUDIT PROBABILITY* to represent tax enforcement and find that these alternative test variables both load positively at the 1 percent level. We observe similar results after excluding potential CIC firms from these two estimations, although the statistical significance is weaker for *DISCLOSED AUDIT PROBABILITY* (one-sided p-value of 0.069). Despite the fact that there are many drawbacks to using disclosed IRS audits to quantify firms' expectations, we continue to find evidence lending support to the prediction in H1.

Other Sensitivity Tests

Next, we consider whether our evidence that IRS monitoring deters tax avoidance is robust to relaxing the assumption of exogeneity of the IRS's auditing decision. For two reasons, our theoretical and empirical treatment of the relation between IRS tax enforcement and corporate tax avoidance to this point assumes that the level of IRS enforcement is exogenously determined. First, our measure of IRS monitoring is the probability that a given firm in a large pool of firms is audited. For its selection of firms to audit, IRS monitoring would be endogenous to corporate tax avoidance only to the extent that one single firm is able to affect the IRS's auditing decisions with respect to the entire pool. Second, there is evidence that the IRS inefficiently allocates resources, and that resources at the IRS are more tied to the political processes that ultimately fund the IRS than by the actual need for IRS tax enforcement.[22] Accordingly, we believe that endogeneity does not pose a serious concern.

In order to confront the threat that this endogenous relationship is spuriously responsible for our inferences, we implement an instrumental variables technique.[23] We specify the number of corporate tax returns filed for the particular asset size class in the previous year as an instrument. Our measure of IRS tax enforcement is the ratio of audits completed in this year in a given IRS asset size class, divided by the number of returns filed in that same asset size class in the previous year. Our choice of instrument relies upon the fact that the variation in *AUDIT PROBABILITY* is induced by both the denominator and numerator in this ratio—variations in actual returns audited by the IRS in each asset class (the numerator, which itself is determined by the IRS and Congress), and variations in the number of returns filed (the denominator, which happens as a result of likely exogenous factors).[24] Our first-stage regression then becomes:

---

[22] Beron et al. (1992) make the assertion that IRS resources are exogenously dispersed geographically, which is challenged in Slemrod and Yitzhaki (2002). Bagchi (2012) finds that IRS funding and enforcement levels reflect political forces.

[23] In another natural approach to tackling potential endogeneity stemming from omitted variables, we report in Table 3 that *AUDIT PROBABILITY* continues to load positively at the 1 percent level when we emphasize the panel structure of our data by estimating firm fixed and random effects models. However, an instrumental variable framework is necessary to handle dynamic endogeneity of firm characteristics.

[24] Finding strong and valid instruments is a vexing problem in tax settings, including ours. Some corporate tax avoidance strategies may actually result in variations in the number of tax returns filed. We assume this effect is negligible. Further, we assume that firms (especially the large firms in our sample) do not avoid taxes by merely neglecting to file a tax return. Finally, general economic conditions may both change the need for more government revenue (increasing IRS audit levels) and decrease the number of returns filed. However, to the extent that we include fixed year effects, constraining our estimation to using within-year variation for identification would only bias our results to the extent that economic conditions affected different-sized firms within the same years differently. To the extent that any of these assumptions are violated, our instrument may be invalid, and the results of this test should be interpreted with caution.

$$AUDIT\ PROBABILITY = \beta_0 + \beta_1 RETURNS\ FILED\ IN_{t-1} + \beta_2 X + \beta_3 INDUSTRY + \beta_4 YEAR + \varepsilon. \quad (2)$$

From Equation (2), we extract fitted values of *AUDIT PROBABILITY*, which we label *AUDIT PROBABILITY HAT*. The first-stage regression (untabulated), indicates that the number of returns filed is an adequate instrument.[25] Next, we estimate the following model:

$$CASH\ ETR = \beta_0 + \beta_1 AUDIT\ PROBABILITY\ HAT + \beta_2 X + \beta_3 INDUSTRY + \beta_4 YEAR + \nu. \quad (3)$$

After using the number of tax returns filed in a given asset size class as an instrument, we obtain results consistent with our previous estimations. The coefficient on *AUDIT PROBABILITY HAT*, 1.73, remains statistically significant at the 1 percent level in the second-stage model as tabulated in Table 4, Panel B, Column (7). Although the magnitude of this coefficient is implausibly large, this regression reinforces that our core result on the prediction in H1 persists even after our attempts to correct for endogeneity. However, we stress that we do not consider endogeneity to be a serious concern given that macro-level IRS auditing policy is largely the result of political forces exogenous to the issues that we are analyzing.[26]

We specify contemporaneous IRS audit rates as our primary test variable under the assumption that managers form rational expectations about the likelihood that firms will experience an IRS audit. Naturally, the actual incidence of IRS audit rates only becomes observable to managers with delay. After relaxing the assumption of rational expectations by replacing *AUDIT PROBABILITY* with its one-year lag in the next regression to ensure that historical rates are known to managers before they settle on the aggressiveness of their firms' tax positions, we still find supportive evidence at the 1 percent level in Column (8) of Table 4, Panel B.[27]

Given that prior tax avoiders tend to be current tax avoiders (e.g., Dyreng et al. 2008; Lisowsky 2010), we add one-year lagged cash ETR to the baseline regression in Column (9) of Table 4, Panel B to control for the persistence in tax avoidance. Predictably, the magnitude of the coefficient for *AUDIT PROBABILITY* falls steeply in this estimation, although this test variable, which now carries a substantially different interpretation, remains positive and highly statistically significant. Our core evidence on the prediction in H1 also holds when we include twice-lagged *CASH ETR* in this specification.

Since we restrict *CASH ETR* to lie between 0 and 1, ordinary least squares (OLS) may result in biased estimates. Data inspection reveals that 9 percent of the *CASH ETR* observations have the value 0 and another 3 percent have the value 1. The evidence reported in Column (10) of Table 4, Panel B confirms that our inferences are materially insensitive to estimating our model with double-censored Tobit. Predictably, the Tobit model yields estimates that are very similar to the OLS estimates given the relatively small amount of censoring in the data (Armstrong et al. 2011).

Another potential concern is that the asset size groups underlying *AUDIT PROBABILITY* reflect nominal dollars, which will gradually translate into an increasing number of firms populating the largest bracket with inflation. In particular, this would be a larger concern if the IRS audited a constant number of firms in each bracket; e.g., the top bracket would be subject to less coverage as the denominator of audit coverage (total number of returns filed) increased, but the number of audits stayed the same. To ensure that inflation is not spuriously behind our results, we eliminate all firms that have changed IRS asset-size categories during our sample period, which leaves only 28,682 observations. In this smaller sample, we still find (untabulated) evidence that *AUDIT PROBABILITY* loads positively at the 1 percent level.[28]

---

[25] Specifically, the coefficient *RETURNS FILED IN* $_{t-1}$ is significant at all conventional levels, and the model has an F-statistic, 2562, that far exceeds 10, which is a standard threshold for delineating weak instruments; e.g., Stock and Watson (2002). Tabulation of the first-stage regression, as well as other analysis and explanation of our instrumental variable strategy, are available from the authors upon request.

[26] Further, Larcker and Rusticus (2009) and Francis and Lennox (2010) stress that corrections for endogeneity that is only potentially a problem routinely generate estimates that are inferior to those obtained by simply using standard ordinary least squares.

[27] Although this is another way to deal with endogeneity, the impact of *AUDIT PROBABILITY* on *CASH ETR* subsides both statistically and economically as we inject more noise into the analysis by moving away from contemporaneous IRS audit rates. Since the IRS can take more than a year to conclude its audit, we also verify that our evidence holds when we integrate several "lead" test variables into the ETR estimations.

Next, large changes in *CASH ETR* might be caused by actual payments to the IRS (and not by decreased avoidance in anticipation of IRS audits). However, this possibility is difficult to rule out. In an attempt to investigate this issue, we first estimate our model on the sample of firms that never mention an IRS settlement in their 10-K, 10-Q, or 8-K filings made with the SEC during our entire sample period (firms with the words "IRS" or "Internal Revenue Service" within ten words of "settlement," a sample that admittedly relies upon firms' disclosure decisions). Although this translates into eliminating 16,508 observations for firms that mention IRS settlements, our main results estimated in Model 1 (in Column 1 of Table 3) still remain.

We also manually inspect the 10-Ks of 50 random firm-years with the largest increases in *CASH ETR* for evidence that these firms made recent settlements with the IRS (i.e., firms that had a *CASH ETR* increase exceeding 10,000 basis points). Of the 50 firm-years, we found that eight firms specifically mention IRS settlements, confirming the importance of our analysis that excludes firms that have ever mentioned an IRS settlement. Our analysis suggests that *CASH ETR*s can drastically change for a variety of reasons, rather than stemming from a single factor.

Isolating Different Portions of the Distribution

Next, we consider whether the role that strict IRS monitoring plays in constraining corporate tax avoidance varies across the distribution of cash ETRs. This involves sharpening the analysis by estimating a simultaneous quantile regression to estimate the impact of *AUDIT PROBABILITY* at the 5th, 10th,. . .,90th, 95th *CASH ETR* quantiles.[29] IRS audit rates may be almost irrelevant to firms near the extremes of the *CASH ETR* distribution. In contrast to firms undertaking tax positions that are very aggressive (meaning that they fully anticipate close IRS scrutiny, and will potentially have lower cash ETRs) or very conservative (meaning that they have nothing to hide, and will potentially have higher cash ETRs), firms toward the middle of this distribution may be more sensitive to corporate tax enforcement. The quantile regression results that we summarize in Figure 2 lend support to this intuition; i.e., we observe that IRS monitoring has a larger impact both economically and statistically for firms between these extremes. This quantile regression analysis does allow other interpretations (e.g., firms near the left end of the *CASH ETR* distribution may simply be those experiencing persistent losses), although it does empirically clarify that the positive relation between IRS monitoring and tax avoidance holds across the vast majority of the distribution.

Supplementary Analysis: The Role of Cross-Sectional Variation in Corporate Governance

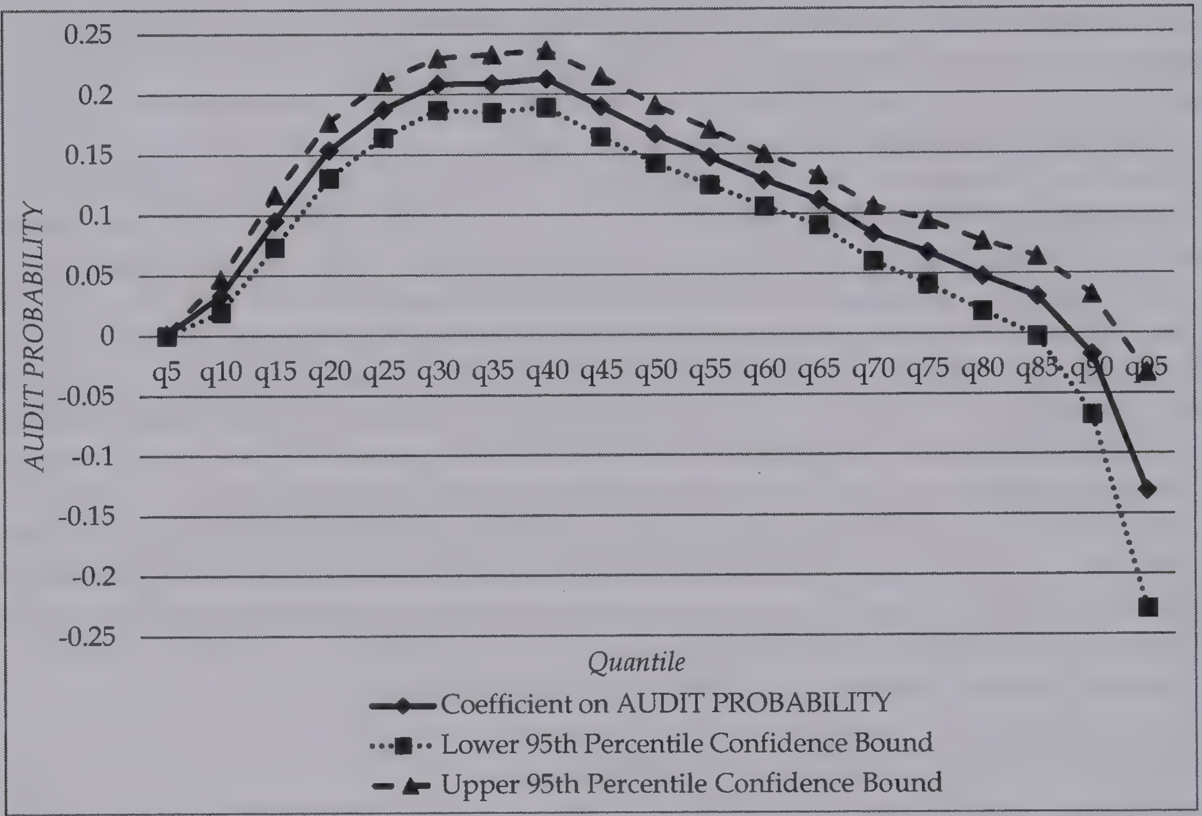
Next, we evaluate whether the impact of close IRS monitoring on disciplining firms intensifies when their corporate governance is relatively poor. Some research suggests that managers rely on the complexity inherent in sophisticated strategies for reducing corporate tax obligations—which

---

[28] Removing firms that have changed size categories disproportionately excludes small firms from the analysis.

[29] A quantile regression estimates the effect at the Xth percentile of the distribution by minimizing the asymmetrically weighted sum of absolute residuals, in contrast to ordinary least squares regression, which estimates the effect at the mean of the distribution by minimizing the sum of squared residuals. See Koenker and Hallock (2001) for a review of work using quantile regressions.

FIGURE 2
Effects of IRS Tax Enforcement on Different Quantiles of *CASH ETR*



This figure depicts the quantile estimates obtained from estimating this equation:

$$CASH\ ETR = \beta_0 + \beta_1 AUDIT\ PROBABILITY + \beta_2 X + Year\ Fixed\ Effects + \varepsilon_{it},$$

on the 5th, 10th, 15th, 20th, 25th, 30th, 35th, 40th, 45th, 50th, 55th, 60th, 65th, 70th, 75th, 80th, 85th, 90th, and 95th quantiles of the distribution of *CASH ETR*. Coefficient values are on the Y-axis and percentiles of the distribution are on the X-axis. The upper and lower 95th percentile confidence intervals surround the coefficient estimates. *AUDIT PROBABILITY* is the number of face-to-face corporate audits completed in IRS fiscal year *t* in a given IRS asset-size category divided by total number of 1120 returns filed in calendar year *t*–1, in an IRS asset-size category. *CASH ETR* is cash taxes paid scaled by pretax income. *X* represents a vector of control variables that are defined in Appendix B: *Log*(*ASSETS*), *LEVERAGE*, *INVENTORY INTENSITY*, *R&D INTENSITY*, *CAPITAL EXPENDITURES*, *ROA*, *NOL*, *ΔNOL*, *FOREIGN INCOME*, and *BIG FOUR*.

they can justify under the guise that lowering taxes benefits shareholders as the residual claimants—to cover their tracks when they are diverting resources from the firms that they run (e.g., Slemrod 2004; Desai 2005). This agency narrative is grounded in the complementarities between corporate tax avoidance and managers' diversionary activities. More recent evidence implies that investors' reactions to managers' attempts to minimize taxes vary across firms according to corporate governance quality (e.g., Desai and Dharmapala 2006, 2009; Guedhami and Pittman 2008; Wilson 2009). However, in the opposite direction, Rego and Wilson (2010) and Seidman and Stomberg (2011) provide evidence that casts some doubt on whether tax sheltering and managerial rent extraction are actually complementary activities.

In extending this line of research, we analyze managers' perceptions by isolating whether the role of external monitoring by the IRS in constraining tax avoidance turns on firm-level governance. Although recent theory (e.g., Desai et al. 2007) and evidence (e.g., El Ghoul et al. 2011) suggest that strict tax enforcement narrows the scope for managers to deprive outside investors by siphoning resources, it follows that firms' own governance institutions will mediate the link between IRS monitoring and corporate tax avoidance. In other words, weak internal governance renders firms more vulnerable to managerial self-dealing hidden through aggressive tax planning, translating into IRS monitoring playing a larger role in reducing tax avoidance in these situations. Consequently, we add a conditioning variable, *GOVERNANCE*, and its interaction with *AUDIT PROBABILITY* to Equation (1) to examine whether the impact of IRS audit rates on constraining aggressive tax planning is concentrated in poorly governed firms.

In successive regressions, this involves focusing on four firm-level governance institutions. After Desai and Dharmapala (2006), El Ghoul et al. (2011), and Kim et al. (2011), we initially gauge *GOVERNANCE* with the index that Gompers et al. (2003) compile according to a count of the presence of 24 anti-takeover provisions that reflect discipline from the market for corporate control. Higher scores indicate when the market for corporate control is more marginalized since defensive tactics entrench incumbent managers. In these cases, governance is worse since the firm becomes less likely to experience an unsolicited takeover bid when the number of provisions is higher. Given the cardinal properties of Gompers et al.'s (2003) index (Cremers and Nair 2005; Larcker et al. 2007), we construct a dummy variable, *HIGH G-INDEX*, that takes the value of 1 when the firm is above the median, and 0 otherwise. We also measure *GOVERNANCE* with the presence of a Big 4 auditor, *BIG FOUR*, known to more tightly constrain managers' discretion over the financial reporting process according to extensive prior research (Francis 2004).[30]

In our next pair of conditioning variables, we shift our focus from external governance to internal governance. We specify our third proxy for *GOVERNANCE* as the fraction of the firm that is owned by institutional investors, which we label *INSTITUTIONAL HOLDINGS*, after Desai and Dharmapala (2006), El Ghoul et al. (2011), and Kim et al. (2011).[31] Isolating institutional investors enables cleaner analysis since other blockholders may be the very corporate insiders who require monitoring. Institutional investors are eager to protect their interests by actively monitoring managers against implementing policies that undermine long-term firm value.[32] We expect to observe that the importance of IRS audit rates to corporate tax avoidance falls when institutional investors hold larger equity positions.

Finally, we sharpen the analysis of the role that institutional shareholders play in moderating the link between corporate tax avoidance and enforcement by separately examining dedicated institutional owners, which we label *DEDICATED INSTITUTIONAL HOLDINGS*, which have even stronger incentives to closely discipline managers toward pursuing long-term value maximization. Recent evidence implying that dedicated, long-term institutions more actively monitor firms helps validate our focus on these investors (e.g., Hartzell and Starks 2003; Chen et al. 2007).[33] We expect that firms with a relatively large number of dedicated institutional owners holding larger equity stakes have better governance characteristics, which, in turn, substitutes for IRS monitoring.

---

[30] We concede that endogeneity in the forms of selection by Big 4 auditors and screening by their clients (e.g., Guedhami et al., 2009) can affect auditor choice. Further, given that auditors can provide tax-related services to their clients, and services provided by a high-quality auditor may be more defensible before the IRS, this may provide an alternative explanation for the results reported in this section related to auditor choice.

[31] There is some evidence that Gompers et al.'s (2003) index that reflects exposure to the market for corporate control complements internal governance through institutional block ownership (Cremers and Nair 2005). However, we concede that there may be links between our conditioning variables; e.g., large institutional shareholders can discipline managers by facilitating takeovers according to prior theory (Shleifer and Vishny 1986) and evidence (Ivashina et al. 2004). Since Gompers et al.'s (2003) index is quite stationary over time and 1998 has the most comprehensive coverage, we also follow Desai and Dharmapala (2006) by using the 1998 version in our analysis. We calculate institutional equity stakes with data from Schedule 13F that firms file with the SEC, which we extract from the Thomson-Reuters Institutional Holdings (13F) database.

[32] It is important to stress at this stage that aggressive tax avoidance may be a positive net present value (NPV) project, although activist institutions may conclude that self-dealing managers will exploit complex tax planning to provide cover when they are denying shareholders by diverting corporate resources.

In Table 6, we report our least-squares estimation results for this analysis. Given that *G-INDEX* reflects worse governance, we expect to observe a positive relation with *CASH ETR* when we interact this conditioning variable with *AUDIT PROBABILITY*. In contrast, since we code our other firm-level governance proxies, *BIG FOUR*, *INSTITUTIONAL HOLDINGS*, and *DEDICATED INSTITUTIONAL HOLDINGS*, so that higher values reflect better governance, we expect a negative relation for their interactions with *AUDIT PROBABILITY*.

The interaction involving *HIGH G-INDEX*, which identifies firms suffering relatively poor discipline from the market for corporate control, loads positively at the 5 percent level in a two-tailed test in Column (1), consistent with IRS monitoring having a stronger impact on deterring corporate tax avoidance in these situations. We follow Desai and Dharmapala (2006) and El Ghoul et al. (2011), among others, in specifying *HIGH G-INDEX* after bisecting the sample according to the count of anti-takeover provisions given the cardinal properties of the underlying data. This evidence persists when we analyze the continuous version of Gompers et al.'s (2003) index, which is allowed to vary by firm-year, in Column (2). Additionally, we continue to find supportive evidence (at the 1 percent level) in Column (3) where we consider firms well governed when they appoint a Big 4 auditor.

In Column (4), we find that the interaction given by the product of *INSTITUTIONAL HOLDINGS* and *AUDIT PROBABILITY* enters negatively at the 1 percent level. This evidence reinforces the intuition that corporate tax avoidance becomes more sensitive to IRS audit rates in the absence of tough external monitoring by institutional shareholders. Similarly, after narrowing the focus in Column (5) to the equity stakes held by dedicated institutional shareholders, the interaction term remains negative and highly statistically significant. In untabulated analysis, the results in Columns (4) and (5) persist if we code the two institutional holdings variables as binary variables. Collectively, the results in Table 6 suggest that the importance of IRS monitoring to constraining firms from undertaking aggressive tax positions rises when firm-level governance is relatively lax, corroborating recent research on the complementarities between managers pursuing aggressive tax planning and their diversionary practices (e.g., Desai and Dharmapala 2006, 2009; Desai et al. 2007; Guedhami and Pittman 2008).

Although our evidence supports recent theory on the interplay between firm-level governance and aggressive tax planning, there are certainly caveats to this finding. Both defining and measuring the type of governance we expect to shape tax planning across firms is difficult, reinforcing that our tests should be interpreted with caution. Moreover, firms' governance reflects their decisions, making it hard to interpret this choice from the standpoint of firm value maximization. Finally, some recent evidence calls into question the empirical relevance of Desai and Dharmapala's (2006) stylized theory. For example, Rego and Wilson (2010) find some results that are hard to square with this theory. Moreover, Seidman and Stomberg (2011) report evidence inconsistent with Desai and Dharmapala's (2006) conclusion that tax sheltering and managers' diversion of corporate resources are complements. Extant research would benefit from additional evidence that helps to clarify whether corporate tax avoidance and managerial rent extraction are complementary activities in practice for a broad sample of U.S. public firms.

---

[33] In contrast, institutions striving to exploit short-lived private information tend to have shorter investment horizons and trade more frequently (e.g., Yan and Zhang 2009; Baik et al. 2010). Moreover, Bushee (1998) documents that the presence of transient institutional shareholders leads to value-destroying activities that increase stock prices only over the short term. He relies on portfolio turnover and concentration measures to sort institutions into dedicated, quasi-indexer, and transient investor categories. We use this classification scheme, which Professor Bushee generously provides on his website.

*, **, *** Denote two-tailed statistical significance at the 10 percent, 5 percent, and 1 percent levels, respectively.
This table presents estimation results from regressing firms' effective tax rates on IRS audit rates, firm-level governance, and controls. Unreported industry controls are based on the Fama and French (1997) industry classification. Beneath each coefficient estimate is reported the t-statistic based on robust standard errors adjusted for clustering by firm. *HIGH G-INDEX* is an indicator variable coded 1 if the firm has an above median value of the Gompers Index Score for firm *i* in 1998. *G-INDEX* is the Gompers Index Score for firm *i* in year *t*. *BIG FOUR* is an indicator variable coded 1 if the firm was audited by a Big 4 auditor in year *t*, and 0 otherwise. *INSTITUTIONAL HOLDINGS* is the portion of the firm held by institutional investors in year *t*. *DEDICATED INSTITUTIONAL HOLDINGS* is the portion of the firm held by dedicated institutional investors in year *t*.
All other variables are defined in the notes to Table 2, and in Appendix B.

V. CONCLUSIONS

We examine whether strict IRS monitoring constrains corporate tax avoidance evident in firms' effective tax rates. In regressions that control for firm size, time, and other determinants, we report robust evidence that firms exhibit less tax avoidance when the IRS imposes tougher enforcement. Our coefficient estimates suggest that raising the probability that the firm will experience an IRS audit from 19 percent (the 25th percentile in our data) to 37 percent (the 75th percentile) is associated with firms' cash effective tax rates increasing by, on average, 7 percent, implying that the importance of IRS monitoring is economically large. In supplementary analysis, we report evidence supporting that the impact of IRS monitoring on corporate tax avoidance intensifies when firm-level governance is worse.

Our research suggests that increases in IRS monitoring decreases corporate tax avoidance, which would stimulate increases in tax revenue. However, the policy implications of this result require careful interpretation. An optimal tax enforcement policy does not necessarily maximize tax revenue net of collection costs, but rather it maximizes societal welfare (assuming that societal welfare maximization defines optimality, a standard assumption in economics that is philosophically controversial; see Mankiw and Weinzierl 2010). Since tax enforcement consumes real resources and produces nothing—rather, it merely transfers private wealth to the state—the optimal enforcement policy often entails less enforcement than would be implied by maximizing tax revenue (Slemrod and Yitzhaki 2002). Moreover, simply increasing the number of audits performed by the IRS may not constitute optimal tax policy given that less costly methods of inducing taxpayer compliance may be available such as promoting cooperation between taxpayers and the IRS (Beck and Lisowsky 2011), requiring more corporate tax disclosure (Hasegawa et al. 2012), and raising the penalty for committing tax evasion (e.g., Becker 1978; Allingham and Sandmo 1972).

APPENDIX A

EXPLANATION OF SURVEY ANALYSIS

In December 2010, we surveyed a portion of the membership of the Tax Executive Institute. A survey was already being administered in order to understand the behavior of multinational firms, and several questions were added as a supplement to that survey. These additional questions were appended to the original survey after it had been sent to the membership by TEI via email 42 days prior, but before a second email was sent to the membership by TEI to ask for their response. After our supplementary questions were added, we received responses from 50 tax directors.[34] We list the questions and responses below:

1. When trying to make tax decisions, do you assess the probability of being audited by a tax authority? (n = 50)

   Yes: 72%
   No: 28%

2. When trying to assess the probability of audit by a tax authority, which of the following sources of information about the tax authority's audit intensity have you used? (Choose as many as apply). (This question was only posed to the 72 percent who answered yes to question 1.) (n = 29)

   Discussions with tax advisor: 93.1%
   Discussions with peer institutions: 51.7%
   Discussions with auditor: 37.9%
   Past audit rates disclosed by the tax authority: 31%
   TRAC data (IRS audit rates) or equivalent: 3.4%

3. From your experience, does a company's assessment of a higher probability of tax authority audit lead the company to: (n = 44)

   Take a less aggressive tax position due to the risk of being challenged: 59.1%
   Have no effect on the tax position taken: 38.6%
   Take a more aggressive tax position for expected bargaining purposes: 2.3%

4. Has the importance of assessing the tax authority's audit probability when making tax decisions changed in the last 10 years? (n = 38)

   It has become much more important: 10.5%
   It has become more important: 44.7%
   It has not changed: 31.6%
   It has become less important: 13.2%
   It has become much less important: 0.0%

---

[34] Both emails were sent to members at 2,700 firms. The original survey was sent 42 days prior to the tax authority supplement, and 172 people had already responded. The response rate for the entire survey period was 8.1 percent, which is comparable to previous surveys of senior executives, including the 9 percent response rate in Graham and Harvey (2001) and 9 percent rate of corporate taxpayers responding to Slemrod and Venkatesch (2002), although it is lower than Graham et al.'s (2011) 26.6 percent response rate.

5. If there is a change in assessed tax risk and a company wanted to alter its plan or position, what percentage of tax plans or positions can be changed? (n = 25)

   Within one month: 12%
   Within six months: 39.6%
   Within one year: 69.2%
   Within two–three years: 91.25%
   Within three–five years: 100%
   Greater than five years: 100%

APPENDIX B
VARIABLE DEFINITIONS

CASH ETR$_{it}$ = cash effective tax rate, cash taxes paid scaled by pretax income (less special items) = $\text{txpd}_{it}/(\text{pi}_{it} - \text{spi}_{it})$;
GAAP ETR$_{it}$ = cash effective tax rate, total tax expense scaled by pretax income = $\text{txt}_{it}/\text{pi}_{it}$;
3-YEAR CASH ETR$_{it}$ = sum of three years cash taxes paid, scaled by the sum of three years of pretax net income = $\sum TXPD_{t,t+1,t+2}/\sum(\text{pi} - \text{spi})_{t,t+1,t+2}$; and
NON-CONFORMING CASH ETR$_{it}$ = cash taxes paid scaled by operating cash flows = $\text{txpd}_{it}/\text{oancf}_{it}$.

Both *CASH ETR* and *GAAP ETR* are set equal to missing if pretax income is negative or zero, and all tax avoidance measures are bound between 0 and 1.

Log(ASSETS)$_{it}$ = ln(Total Assets) = $\ln(\text{at}_{it})$;
Log(MVE)$_{it-1}$ = ln(Market Value of Equity) = $\ln(\text{prcc\_f}_{it-1} * \text{csho}_{it-1})$;
Log(SALES)$_{it}$ = ln(Total Sales) = $\ln(\text{sale}_{it})$;
LEVERAGE$_{it}$ = total long-term debt scaled by lagged assets = $\text{dltt}_{it}/\text{at}_{it-1}$;
INVENTORY INTENSITY$_{it}$ = total inventory scaled by lagged assets = $\text{invt}_{it}/\text{at}_{it-1}$;
R&D INTENSITY$_{it}$ = research and development expense scaled by lagged assets = $\text{xrd}_{it}/\text{sale}_{it}$; if xrd is missing, then rdint is set to 0;
CAPITAL EXPENDITURES$_{it}$ = total capital expenditures scaled by lagged assets = $\text{capx}_{it}/\text{at}_{it-1}$;
ROA$_{it}$ = pretax income divided by assets = $\text{pi}_{it}/\text{at}_{it}$;
NOL$_{it}$ = indicator variable coded 1 if firm has a tax loss carry forward (tlcf < 0), 0 otherwise;
ΔNOL$_{it}$ = difference between last year's NOL carry forward and this year's NOL carry forward, scaled by lagged assets = $(\text{tlcf}_{it} - \text{tlcf}_{it-1})/\text{at}_{it-1}$;
FOREIGN INCOME$_{it}$ = amount of foreign income earning by a firm, scaled by lagged assets = $\text{pifo}_{it}/\text{at}_{it-1}$;
BIG FOUR$_{it}$ = indicator variable coded as 1 if the firm appoints a Big 4 auditor in year *t*, 0 otherwise;
AUDIT PROBABILITY$_{ts}$ = number of face-to-face corporate audits completed in IRS fiscal year *t* in asset class a, divided by total number of 1120s filed in calendar year *t*–1 in asset class a;
HIGH G-INDEX$_{i}$ = indicator variable coded 1 if the firm has an above median value of the Gompers Index Score for firm *i* in 1998, 0 otherwise; the G-Index is the sum of 24 corporate governance rules, higher numbers indicate worst corporate governance, as derived in Gompers et al. (2003);
G-INDEX$_{it}$ = Gompers Index Score for firm *i*; the G-Index is the sum of 24 corporate governance rules, higher numbers indicate worst corporate governance, as derived in Gompers et al. (2003);

$INSTITUTIONAL\ HOLDINGS_{it}$ = percentage of the firm's equity held by institutional investors in year *t*; calculated from data provided in the Thomson-Reuter's Institutional Holdings (13F) Database;

$DEDICATED\ INSTITUTIONAL\ HOLDINGS_{it}$ = percentage of the firm's equity held by dedicated institutional investors in year *t*, classified using Bushee (1998);

$DISTRICT/SIZE/TIME\ AUDIT\ PROBABILITY_{tsd}$ = number of corporate tax audits completed in IRS fiscal year *t* in an IRS district for a IRS asset class group, divided by the number of corporate tax returns in the same district and IRS asset size group in IRS calendar year $t-1$; and

$DISTRICT/TIME\ AUDIT\ PROBABILITY_{ts}$ = number of corporate tax audits completed in IRS fiscal year *t* in a given IRS district, divided by the number of corporate tax returns received in that same district in IRS calendar year $t-1$.

All continuous variables are winsorized at the 1st and 99th percentiles.

Materiality Judgments and the Resolution of Detected Misstatements: The Role of Managers, Auditors, and Audit Committees

Marsha B. Keune
University of South Carolina

Karla M. Johnstone
University of Wisconsin–Madison

ABSTRACT: This study investigates how manager and auditor incentives, along with audit committee characteristics, are associated with materiality judgments about detected misstatements. Using data on detected misstatements that occurred between 2003 and 2006, we find auditors' incentives to protect their reputations weaken the effect of managerial incentives associated with the pressure created by analyst following; auditors are less likely to allow managers to waive material misstatements as audit fees increase. Regarding audit committee characteristics, results reveal that audit committees with greater financial expertise are less likely to allow managers to waive material misstatements compared to audit committees with less expertise.

Keywords: *audit committees; audit fees; error correction; materiality; stock analysts.*

Data Availability: *Data used in the study are available from public sources.*

I. INTRODUCTION

Auditors detect and inform client managers and audit committees of misstatements, and these agents must reach agreement about whether managers will correct the misstatements prior to issuing the financial statements. Managers may waive correcting misstatements if auditors and audit committees conclude that the misstatements do not render the financial statements *materially* incorrect. Yet, the Securities and Exchange Commission (SEC) and others have asked the rhetorical question: If a misstatement is immaterial, then why not correct it (Levitt 1998)? Given the absence of bright-line criteria for assessing materiality,

judgments about resolving misstatements may be strategic to achieve desired financial reporting outcomes (Acito et al. 2009). Analysis of the role of managers, auditors, and audit committees in misstatement materiality judgments is therefore important because it can aid understanding of observed audit and financial reporting outcomes that can affect users. However, such analysis has been difficult to pursue because information on materiality judgments in resolving detected misstatements either has not been publicly observable (Kinney and Libby 2002; Nelson et al. 2002) or has been limited to specific industries or financial issues (e.g., lease accounting as in Acito et al. [2009]).

In this study we make use of regulation concerning the resolution of detected misstatements contained in Staff Accounting Bulletin No. 108 (SAB 108). The implementation of SAB 108 provides disclosure data on detected misstatements that were previously judged immaterial and were not corrected in the financial statements until the release of the new guidance (SEC 2006). We use the SAB 108 disclosures to measure both the qualitative and the quantitative materiality of misstatements during the periods in which they remained uncorrected.[1] Using these disclosures, we test a conceptual model of the manager-auditor-audit committee resolution process for detected misstatements that includes analysis of how qualitative and quantitative materiality judgments about detected misstatements are influenced by managers' incentives, auditors' incentives, and audit committee characteristics.

SAB 108 became effective for annual financial statements covering the first fiscal year-end after November 15, 2006. Prior to SAB 108, the quantitative materiality of detected misstatements was evaluated using either a balance sheet *or* an income statement approach. The income statement approach focuses on the materiality of current-year misstatements and the effect of reversing prior-year misstatements on the income statement, which may allow misstatements to accumulate on the balance sheet. The balance sheet approach focuses on ensuring the year-end balance sheet is correct. Audit firms' client portfolios historically varied in the use of these approaches (Nelson et al. 2005; Keune and Johnstone 2009). In contrast, SAB 108 requires using a "dual approach" (SEC 2006), applying *both* the balance sheet and the income statement approaches. Upon adopting SAB 108, companies with misstatements judged material under the dual approach could correct the prior-period misstatements by recording a one-time cumulative transition adjustment to retained earnings, adjusting current-year earnings, or restating financial statements (SEC 2006). Our sample consists of misstatements that were detected but remained uncorrected prior to the adoption of SAB 108, as they were initially judged immaterial using the materiality and correction guidance in effect at the time of detection.

Before stating our results and contributions, we acknowledge features of our data that limit one's ability to make inferences about audit quality based on SAB 108 misstatement corrections. As we note above, the misstatements in our sample were judged immaterial at the time of detection. Considering the size of these misstatements, we find that while the largest is greater than 50 percent of normal income, the median misstatement is 2 percent of normal income. This implies that some auditors detected relatively small misstatements, and the detection of small misstatements is one indication of high audit quality. Thus, the mere fact that a company corrected and disclosed prior-period misstatements when adopting SAB 108 does not necessarily indicate low audit quality. It is therefore an open question as to whether auditors, managers, and audit committees should be criticized for not correcting the misstatements earlier, or commended for complying with SAB 108 by disclosing and correcting the misstatements. Further, we note that managers cannot waive the correction of a misstatement unless a misstatement exists, and the distribution of misstatements across companies and their auditors may not be random or exogenous. Thus, readers should consider our inferences in light of the fact that our sample only comprises companies for which a misstatement exists. Given these caveats, we are circumspect in our inferences regarding the association between audit quality and SAB 108 misstatement corrections. Instead, we focus our analyses and inferences on the impact of proxies for managers' and auditors' incentives, as well as audit committee characteristics, on our measures of the qualitative and quantitative materiality of waived misstatements.

---

[1] During our sample period, determining materiality involves evaluating whether a misstatement will affect the judgments of a "reasonable person" (FASB 1980). The SEC (1999) issued Staff Accounting Bulletin No. 99 (SAB 99), which requires consideration of both quantitative and qualitative characteristics when judging misstatement materiality. Quantitative characteristics concern the size of a misstatement in relation to the overall financial statements and are often based on income statement components (Holstrum and Messier 1982; Brody et al. 2003; Messier et al. 2005). Qualitative characteristics concern the effect of a misstatement in relation to users' decisions. SAB 99 identifies considerations that would cause a quantitatively small misstatement to be qualitatively material, which includes whether the misstatement hides a failure to meet analysts' consensus expectations for the company.

We first test the association between the qualitative characteristics of misstatements and managers' incentives as proxied by analyst following. We construct a unique new variable using SAB 108 misstatement and analysts' forecast data that enables us to identify companies that meet or beat analysts' consensus forecasts by waiving the correction of misstatements. In other words, the qualitatively material misstatements in our sample, if corrected, would have resulted in the respective companies missing analysts' consensus forecasts. We find that managers are generally more likely to waive qualitatively material misstatements as analyst following increases, but this effect is primarily present when audit fees are relatively low. This result extends the materiality literature by illustrating the role of managers' incentives in materiality judgments and the use of materiality justifications to achieve desirable financial reporting outcomes (Acito et al. 2009), as well as the curtailing effect that auditors of high-fee clients have on managers' behavior. Further, by using publicly available data, we complement prior archival (Wright and Wright 1997), survey (Nelson et al. 2002, 2003), and experimental research (Libby and Kinney 2000; Braun 2001; Nelson et al. 2005; DeZoort et al. 2006; Ng 2007; Ng and Tan 2007) on materiality judgments in which earnings management is a concern.

Next, we test the association between audit fees and the likelihood that auditors will allow managers to waive material misstatements. One theory suggests that economic dependence exists between auditors and their clients, with auditors catering to managers' demands (e.g., DeAngelo 1981b; Beck et al. 1988; Magee and Tseng 1990). A competing theory suggests that auditors protect their reputations by rejecting managers' demands when the downside risk to doing so is high (Reynolds and Francis 2001; Larcker and Richardson 2004). Consistent with the theory of auditor reputation protection, we find auditors are less likely to allow managers to waive quantitatively material misstatements as audit fees increase. We also find a negative interaction between audit fees and analyst pressure on the likelihood that auditors will allow managers to waive qualitatively material misstatements. Specifically, auditors' incentives to protect their reputations weaken the effect of managerial incentives associated with the pressure created by analyst following; auditors are less likely to allow managers to waive qualitatively material misstatements as audit fees increase. These results extend the literature on auditor independence in relation to professional services fees. Prior studies examine the relation between such fees and various proxies for audit and financial reporting quality (for instance, accounting accruals, auditors' going-concern reports, and restatements; see, e.g., Reynolds and Francis 2001; Frankel et al. 2002; Geiger and Rama 2003; Kinney et al. 2004; Larcker and Richardson 2004). Our study complements this literature by providing evidence on the association between audit fees and the materiality of waived misstatements.

In our last set of tests, we follow the recommendation of Caskey et al. (2010) to include audit committee characteristics in analyses concerning decisions made by auditors and managers. SAS 89 requires that audit committees be informed of auditors' and managers' judgments about

misstatements. We examine the effect of audit committee expertise on the likelihood of detected material misstatements being waived. We find that audit committees with greater financial expertise are less likely to allow managers to waive qualitatively or quantitatively material misstatements than are audit committees with less expertise. These results extend prior research on the role of audit committee characteristics in judgments (e.g., Abbott et al. 2004).

In Section II we detail the manager-auditor-audit committee resolution process for detected misstatements and describe academic theory underlying our hypotheses. We describe our research design in Section III and present our results in Section IV. Section V concludes.

II. BACKGROUND AND HYPOTHESES

The Manager-Auditor-Audit Committee Resolution Process for Detected Misstatements

Figure 1 depicts a conceptual model that describes the manager-auditor-audit committee resolution process that occurs upon misstatement detection. Managers, auditors, and audit committees begin by evaluating the misstatement (Phase One). These agents' respective incentives and professional characteristics then affect judgments related to the misstatement (Phase Two), including interpretations of professional standards on materiality (Phase Three). These judgments thus affect misstatement correction decisions (Phase Four). This resolution process involves judgment because materiality assessments are not based on simple bright-line thresholds (SEC 1999) and provide auditors with an opportunity to curtail aggressive manager choices during misstatement evaluation (Nelson et al. 2002; Trotman et al. 2005; Sanchez et al. 2007).

Managers' Incentives and the Resolution of Detected Misstatements

Analyst coverage, as well as compensation contracts, create incentives for managers to manage earnings (Levitt 1998; Matsunaga and Park 2001; Brown and Caylor 2005; Burns and Kedia 2006).[2] For example, Graham et al. (2005) report that CFOs work to meet or beat earnings benchmarks to achieve credibility in the capital markets, maintain or increase stock prices, enhance managers' reputations, and convey future corporate growth prospects. Similarly, Dhaliwal et al. (2004) find that managers actively manage earnings to meet analysts' forecasts, and Cheng and Warfield (2005) find a positive association between the number of analysts covering a company and earnings reports that meet or just beat analysts' forecasts. Bartov et al. (2002) provide an explanation for this relation by showing that companies that meet or beat analysts' earnings expectations have higher quarterly returns than companies with similar forecast errors that do not meet expectations. Importantly, their results show that the premium to meeting or beating persists even when achieved via earnings management.

A prominent earnings management benchmark is thus meeting or beating analysts' consensus forecasts (Ashbaugh et al. 2003; Lim and Tan 2008). Indeed, archival research reveals that auditors judge a pattern of just meeting consensus forecasts as the most common indicator of a client's earnings management risk (Bedard and Johnstone 2004). SAB 99 recognizes that a misstatement that hides a failure to meet analysts' consensus forecast can be qualitatively material even if it is quantitatively immaterial. Using SAB 108 data, we identify misstatements that enabled companies to meet or beat analysts' consensus forecasts; if those same misstatements had instead been corrected, the corrections would have resulted in the companies missing analysts' consensus forecasts.[3] Based on this discussion, we predict that the level of analyst following is positively related to the likelihood that managers will waive correcting misstatements that, if corrected, would cause the company to miss its consensus forecast:

> **H1:** Analyst following increases the likelihood that managers will waive material misstatements.

Auditors' Incentives and the Resolution of Detected Misstatements

The theory of economic dependence suggests that auditors are dependent on clients and cater to managers' financial reporting demands to earn future fees (e.g., DeAngelo 1981a, 1981b; Beck et al. 1988; Magee and Tseng 1990; Johnstone et al. 2001; Kinney and Libby 2002). Some research supports this theory (e.g., Frankel et al. 2002; Ashbaugh et al. 2003; Hoitash et al. 2007; Hatfield et al. 2008; Lim and Tan 2008). For example, Libby and Kinney (2000) show that auditors consider a correction of an earnings overstatement to be less likely if it would cause a missed forecast. Ng (2007) reports that auditors are less likely to require correction of a quantitatively immaterial misstatement when doing so would cause the company to miss analysts' forecasts compared to when it would disrupt the prior-year earnings trend, and Ng and Tan (2007) show that auditors are less likely to require correction of a quantitatively immaterial audit difference that affects the company's ability to meet analysts' consensus forecasts when the manager expresses concern about adverse consequences.

---

[2] We acknowledge that some prior literature characterizes analysts as external monitors who reduce managers' incentives and ability to manage earnings (e.g., Jensen and Meckling 1976; Healy and Palepu 2001).

[3] We measure and interpret qualitative materiality consistent with experimental studies that examine situations in which waiving a misstatement allows a client to meet or beat analysts' consensus forecasts (e.g., Ng and Tan 2007).

In our setting, the theory of economic dependence suggests that auditors are more likely to allow managers to waive material misstatements as their economic dependence increases, implying a positive relation between audit fees and the likelihood of managers waiving material misstatements. As audit fees increase, auditors face greater future income risk (DeAngelo 1981a, 1981b), which provides managers the incentive to pressure auditors to allow them to waive misstatements (Wright and Wright 1997; Nelson et al. 2002).

While there is support for the theory of economic dependence, other results in the literature are inconsistent with this theory. Braun (2001) shows that auditors' decisions to allow managers to waive a material misstatement are not influenced by the size of a client's audit fees in relation to the local office's total fees, and that auditors are less likely to allow managers to waive a material misstatement when the company or misstatement poses greater auditor litigation risk. Other experimental research finds that auditors are unwilling to allow managers to waive misstatements, even when future audit fees are at risk (Hatfield et al. 2008). Archival research examining auditors' incentives and the meet-or-beat benchmark finds no association between audit fees and companies meeting or beating forecasts (Ashbaugh et al. 2003; Lim and Tan 2008). Taken together, this work implies that auditors' reputational incentives also play a role.

The theory of reputation protection suggests that auditors value their reputations, identify risks posed by their clients, and respond by exerting effort (Bedard and Johnstone 2004) so as to protect their reputations and reduce litigation risk (e.g., Stice 1991; Lys and Watts 1994; Johnstone and Bedard 2001). Some prior research provides evidence supporting this theory (e.g., Reynolds and Francis 2001; Larcker and Richardson 2004; Mitra et al. 2009). In our setting, the theory of reputation protection predicts that auditors are less likely to allow managers to waive material misstatements as the downside risk of reputation loss increases with audit fees, which implies a negative relation between audit fees and the likelihood that a manager waives a material misstatement. Reputation loss associated with relatively high audit fees is especially relevant during our sample period because audit fees are publicly available. Larcker and Richardson (2004, 625) find a negative relation between the level of audit fees and the size of discretionary accruals, which the authors attribute to "auditor behavior being constrained by reputation effects." In essence, as audit fees increase, the auditor experiences greater reputation risk due to increased visibility, which leads to less willingness to allow managers to waive material misstatements. Also consistent with the theory of reputation protection, research shows that auditors require clients with lower financial reporting quality to pay higher audit fees to compensate for the extra time required to perform necessary audit work (Kinney et al. 2004). In our setting, this implies that auditors that charge higher (lower) fees perform more (less) audit work and are less (more) likely to allow managers to waive material misstatements.

Based on these mixed results concerning the effects of auditors' incentives, we make the following nondirectional prediction regarding the association between audit fees and the likelihood that auditors will allow managers to waive material misstatements:

H2: Audit fees affect the likelihood that auditors will allow managers to waive material misstatements.

Of course, we study a setting in which managers decide whether to correct detected misstatements *and* auditors decide whether to agree with managers' decisions. Thus, the joint role of managers' incentives to manage earnings and auditors' incentives to allow managers to manage earnings is important (Antle and Nalebuff 1991; Levitt 1998; Kinney and Libby 2002; Nelson et al. 2002). Prior research examining the use of auditors' materiality judgments to meet or beat analysts' forecasts focuses on the role of analysts' forecasts and managers' incentives, but has not explicitly considered the role of auditors' incentives.

To understand how auditors' and managers' incentives interact, first assume that analyst pressure increases the likelihood that managers will waive material misstatements. If auditors make judgments consistent with reputation protection, then they will be less likely to allow managers to waive material misstatements as audit fees increase (i.e., a negative interaction between audit fees and analyst pressure). However, if auditors make judgments consistent with the theory of economic dependence, they will be more likely to allow managers to waive material misstatements as audit fees increase (i.e., a positive interaction between audit fees and analyst pressure). Given these competing possibilities and the lack of empirical research in this area, we test a nondirectional prediction regarding the interaction between managers' and auditors' incentives and the likelihood that auditors will allow managers to waive correcting misstatements that, if corrected, would cause the company to miss its consensus forecast:

H3: The interaction between analyst following and audit fees affects the likelihood that auditors will allow managers to waive material misstatements.

Audit Committee Financial Expertise and the Resolution of Detected Misstatements

SAS 89 requires auditors to inform the audit committee about significant adjustments affecting the financial reporting process (paragraph .09) and about uncorrected misstatements that managers have judged immaterial (paragraph .10). These requirements allow audit committee oversight of misstatement resolution (Johnstone et al. 2001; Cohen et al. 2002, 2010; Ng and Tan 2003). We expect audit committee financial expertise to affect this oversight role.

Prior research shows that an audit committee's expertise affects its performance. Abbott et al. (2004) report a negative association between audit committee financial expertise and the presence of restatements, and Farber (2005) shows that companies experiencing fraud have fewer audit committee financial experts. In our setting, we expect that audit committees with greater financial expertise are more familiar with materiality concepts and hence are less likely to allow managers to waive material misstatements than are those with less expertise. Therefore, we make the following prediction with respect to the relation between audit committee financial expertise and the likelihood that managers will waive material misstatements:

H4: Audit committees with more financial expertise decrease the likelihood that managers will waive material misstatements.

III. RESEARCH DESIGN

Sample Description

Our data-collection period covers 10-Qs filed from November 15, 2006 to February 28, 2007 and 10-Ks filed from November 15, 2006 to February 15, 2008, and our analyses examine waived misstatements that existed in the financial statements during the period January 1, 2003 to September 30, 2006.[4] To identify these misstatements, we read SAB 108 disclosures to find companies that corrected misstatements under SAB 108.[5] The calculations of our dependent and control variables require that companies disclose misstatement-type descriptions (e.g., derivative, business combination, or revenue) and individual misstatement amounts during specific years in our sample period.[6] Our sample includes individual misstatements in financial statements in a specific year. We conduct our tests at the individual misstatement level to avoid netting or aggregating misstatements and to control for the accounting complexity of misstatements.

---

[4] Although some SAB 108 companies did disclose misstatements that existed prior to this period, we restrict our sample to examine the period after the Sarbanes-Oxley Act of 2002 (SOX) because the introduction of SOX could have changed the misstatement resolution process.

[5] An example of a SAB 108 disclosure is available in Keune and Johnstone (2009, Exhibit 1).

Table 1, Panel A reports sample selection information, while Panels B and C report industry and year concentrations. The sample initially consists of 1,290 SAB 108 misstatements with necessary information. We eliminate 295 misstatements detected and corrected by companies in the year of SAB 108 implementation. These misstatements differ from other SAB 108 misstatements because they were not evaluated by auditors, managers, and audit committees in past periods. Next, we eliminate 32 misstatements related to non-U.S. and holding firms, 7 misstatements without Compustat data, 87 misstatements without Audit Analytics data, and 86 misstatements without audit committee and governance data. We estimate Model 3 (detailed below), which examines quantitatively material misstatements using a normal income measure, on this sample of 783 misstatements. Model 2 (detailed below) examines quantitatively material misstatements using a pretax income measure, which requires removing 200 additional misstatements at companies with current-year losses and small profits. Model 1 (detailed below) examines misstatements that allowed companies to meet or beat analysts' median consensus forecasts. To arrive at the sample of 340 misstatements for this model, we eliminate from the Model 3 sample 178 misstatements without I/B/E/S data and 265 misstatements for companies that did not meet or beat analysts' median consensus forecasts.

Model 1: Qualitative Materiality

We test H1–H4 by estimating three logit regression models (collectively "Model 1a, 1b, and 1c" or "Model 1") in which the dependent variable includes a benchmark test relating to meeting or beating analysts' consensus forecasts. Our first model is Model 1a:

$$\begin{aligned} QUAL\_MATERIAL = {} & \alpha + \beta_1 ANALYST + \beta_2 FEE + \beta_3 ANALYST \times FEE + \beta_4 ACEXP \\ & + \beta_5 ACMTG + \beta_6 MIS\_TYPE + \beta_7 TENURE + \beta_8 BIG\_N \\ & + \beta_9 BLOCK + \beta_{10} CEOCOB + \beta_{11} INVREC + \beta_{12} AGE + \beta_{13} MW \\ & + \beta_{14} LITRISK + \beta_{15} LOSS + \beta_{16} SEG + \beta_{17} SALESGROWTH \\ & + \beta_{18} ASSETS + \beta_{19} Industry_i + \beta_{20} Year_i + \varepsilon. \end{aligned} \tag{1a}$$

To capture the use of misstatements to meet or beat analysts' consensus forecasts, we compare the per-share effect of each individual misstatement to the relevant analyst consensus forecast for year *t*. Our proxy for qualitative materiality, *QUAL_MATERIAL*, equals 1 if, in year *t*, a company reported basic earnings per share (EPS) that meets or beats the last median consensus forecast before the earnings report but would have missed the forecast if the company corrected the misstatement amount affecting net income during year *t*, and equals 0 otherwise.[7] Appendix A illustrates measurement of the dependent variables, and Table 2 provides variable definitions.

Hypothesis-Testing Independent Variables

We measure analyst following as the log of the number of analysts' forecasts used to determine the consensus forecast, *ANALYST*. To capture audit fees, *FEE*, we employ four complementary measures. First, we analyze the magnitude of audit fees, *LNAUDIT*, which we measure as the

---

[6] Consequently, our analyses do not include misstatements for which the company did not provide sufficient disclosure to allow us to ascertain the misstatement amounts present in the financial statements.

[7] Other benchmarks mentioned in SAB 99 include reporting net income versus net loss and reporting an earnings increase versus earnings decrease from the prior year. We are unable to conduct tests using these benchmarks due to the low frequency of SAB 108 misstatements used to achieve these benchmarks ($n \leq 20$ for each benchmark).

TABLE 1

Misstatements Sample

Panel A: Number of Misstatements

	Models 1 and 3	Model 2
Misstatements with identifying data	1,290	
Less: Misstatements detected by companies in the same year the misstatements were corrected	295	
Less: Non-U.S. and holding companies	32	
Less: Compustat missing data	7

TABLE 2

Variable Definitions

Variable Name		Description
Dependent Variables		
QUAL_MATERIAL	=	1 if company reported basic EPS that meet or beat last analysts' median consensus forecast before earnings report, but would have missed the forecast if it corrected the income statement misstatement, 0 otherwise;
QUANT_MATERIAL_PRETAX	=	1 if abs(larger of income statement or balance sheet misstatement amount/pretax income using Compustat "pi") is $\geq$ 5 percent, 0 otherwise; and
QUANT_MATERIAL_NORM	=	1 if abs(larger of income statement or balance sheet misstatement amount/normal income) is $\geq$ 5 percent, 0 otherwise.
Independent Variables		
ANALYST	=	ln(analysts' forecasts determining consensus) using I/B/E/S "numest";
FEE	=	*LNAUDIT*, *ABNORMALAUDIT*, *OFFICEAUDIT*, and *FIRMAUDIT*;
LNAUDIT	=	ln(Audit Fees) from Audit Analytics;
ABNORMALAUDIT	=	residual (i.e., *LNAUDIT* − predicted value) from audit fee estimation model where a negative (positive) value implies audit fees lower (higher) than predicted for auditor's effort and risk;
OFFICEAUDIT	=	fractional percentile rank of client's audit fees within opinion issuing office of the audit firm in Audit Analytics where higher values imply larger fees;
FIRMAUDIT	=	fractional percentile rank of client's audit fees within auditor's firm in Audit Analytics where higher values imply larger fees; and
ACEXP	=	percentage of audit committee members with financial expertise.
Control Variables		
FE_NOSCALE	=	$\lvert$[(reported earnings − waived error) − consensus forecast]$\rvert$;
FE_SCALED	=	$\lvert$[(reported earnings − waived error) − consensus forecast]/End of year common stock price$\rvert$ × 100;
ACMTG	=	number of audit committee meetings during the year;
MIS_TYPE	=	1 if revenue, reserve, tax, derivative, business combination, lease, pension, or stock option misstatement, 0 otherwise;
TENURE	=	1 if auditor tenure in Audit Analytics is three or more years, 0 otherwise;
BIG_N	=	1 if KPMG, PricewaterhouseCoopers, Deloitte, or Ernst & Young is auditor in Audit Analytics, 0 otherwise;
BLOCK	=	1 if any stockholder other than a manager or director owns more than 5 percent of outstanding shares, 0 otherwise;
CEOCOB	=	1 if the CEO serves as the chair of the board of directors, 0 otherwise;
INVREC	=	sum of total inventory (Compustat "invt") and total receivables (Compustat "rect") deflated by total assets (Compustat "at");
AGE	=	ln(data year − first year company listed in Compustat);

(continued on next page)

TABLE 2 (continued)

Variable Name		Description
MW	=	1 if SOX Section 302 or 404 material weakness is reported in 10-K according to Audit Analytics, 0 otherwise;
LITRISK	=	1 if industry is 2833–2836, 8731–8734, 3570–3577, 7370–7374, 3600–3674, 5200–5961, 0 otherwise;
LOSS	=	1 if net loss in any of last three years (using Compustat "ib"), 0 otherwise;
SEG	=	ln(number of business segments from Compustat segment file);
SALESGROWTH	=	(current year net sales − prior year net sales)/prior year net sales (using Compustat "sale");
ASSETS	=	ln(total assets) using Compustat "at";
Industry	=	industry indicator variables are SIC 01–14, SIC 15–19, SIC 20–21, SIC 22–23, SIC 24–27, SIC 28–32, SIC 33–34, SIC 35–39, SIC 40–48, SIC 49, SIC 50–52, SIC 53–59, SIC 60–69, and SIC 70–79; and
Year	=	year indicator variables.

natural logarithm of audit fees. As noted by Wright and Wright (1997, 20), "the larger the audit fees, the greater is the risk to future income and the higher is the incentive to waive adjustments consistent with client pressures." The empirical question that we address is whether auditors acquiesce to this pressure in a setting in which third parties can observe audit fees.

Second, we examine a client's abnormal or unexpected audit fees, *ABNORMALAUDIT*, measured using the residual from a model predicting *LNAUDIT*.[8] Consistent with Larcker and Richardson (2004), we expect auditors' behavior to vary depending on whether they are paid more or less for the audit than a relevant economic benchmark. If the abnormal fee is less than or equal to 0, then auditors presumably have little to lose by insisting that managers correct the misstatement because their audit fees are not commensurate with engagement risk and effort. If the abnormal fee is greater than 0, in contrast, then auditors are likely to feel greater pressure to maintain the relationship with the client. However, in this setting auditors' judgments may not necessarily be biased in favor of managers' preferences. Instead, auditors in the post-SOX period may have competing incentives to charge abnormally high audit fees to perform additional work to protect their reputations and avoid second-guessing by regulators and third-party observers.

Our third and fourth measures of audit fees are the fractional rank of the client's audit fees within the opinion-issuing office of the audit firm, *OFFICEAUDIT*, which represents the importance of the client to the office and its partners, and the fractional rank of the client's audit fees within the opinion-issuing firm, *FIRMAUDIT*, which represents the importance of the client to the entire firm and its partners.[9] Client importance could motivate auditors to allow managers to waive misstatements.

---

[8] To predict *LNAUDIT*, we estimate the following model from Larcker and Richardson (2004), which is based on Simunic (1984) and Craswell et al. (1995) and uses a sample of 12,236 firm-years from Compustat and Audit Analytics: $LNAUDIT = \alpha + \beta_1 ASSETS + \beta_2 SEG + \beta_3 INVREC + \beta_4 DEBT + \beta_5 INCOME + \beta_6 LOSS + \beta_7 GC + \beta_8 MW + \beta_9 Industry_i$; where *DEBT* = (debt in current and long-term liabilities, Compustat "dlc" and "dltt")/total assets (Compustat "at"); *INCOME* = operating income after depreciation (Compustat "oiadp")/total assets (Compustat "at"); *GC* = 1 if there is a going concern opinion in Audit Analytics, and 0 otherwise; and all other variables are as defined in Table 2. The model predicts *LNAUDIT* with an Adjusted R^2 of 0.711, which is comparable to the Adjusted R^2 of 0.749 for total fees reported by Larcker and Richardson (2004).

[9] The fractional rank variable ranges from 0.01 to 1.00, where 0.01 (1.00) is the smallest (largest) client within the sub-population.

Frankel et al. (2002), however, find that the rank of the client's fees within the audit firm is negatively associated with various earnings management measures including earnings surprises and the magnitude of absolute, income-increasing, and income-decreasing discretionary accruals. They interpret these results as indicating that the client's financial importance and visibility provide the audit firm with incentives to invest in its reputational capital. Consistent with prior research, we posit that investments in reputational capital and risk management likely occur through increased audit effort (Bedard and Johnstone 2004; Kinney et al. 2004). In sum, our four audit fee measures capture potentially divergent incentives: the pressure to acquiesce to managers' demands and the pressure to maintain a valuable reputation. Our final hypothesis-testing variable measures audit committee financial expertise, *ACEXP*, as the percentage of audit committee members with financial expertise.[10]

Control Variables

We control for audit committee diligence using the number of audit committee meetings during the year, *ACMTG*.[11] Abbott et al. (2004) report a negative association between the number of audit committee meetings and restatements, suggesting that more diligent audit committees provide more rigorous oversight. Similarly, Farber (2005) shows that companies experiencing fraud have less diligent audit committees. These results suggest that audit committees that meet more frequently may be less likely to allow managers to waive material misstatements. However, audit committees may also have more meetings in order to evaluate and resolve issues concerning the misstatements. Thus, we make no directional prediction for the relation between material waived misstatements and the number of audit committee meetings.

We control for the complexity of the misstatement using *MIS_TYPE*, which is an indicator variable equal to 1 if the misstatement involves complex accounting judgments, and 0 otherwise. Consistent with prior research, we expect that complex misstatements are more likely to be material (Keune and Johnstone 2009). Next, we control for the length of an auditor-client relationship using *TENURE*, an indicator variable equal to 1 if the auditor-client relationship has been in effect three or more years, and 0 otherwise. Dopuch et al. (2001) suggest that longer-tenured auditors display reduced independence, but other research shows that companies with short (long) auditor relationships are associated with higher (lower) audit and financial reporting quality (Geiger and Raghunandan 2002; Johnson et al. 2002; Myers et al. 2003; Carcello and Nagy 2004). Thus, we make no directional prediction for *TENURE*.[12] We control for audit firm size using the indicator variable *BIG_N*. Although large audit firms may be associated with higher audit quality (DeAngelo 1981a, 1981b) and audit fees (Ashbaugh et al. 2003), no prior research suggests that Big N audit firms are more or less likely to allow managers to waive a material misstatement, so we make no directional prediction for this variable.

---

[10] We define audit committee financial experts as members with accounting expertise (i.e., Certified Public Accountants, Chartered Accountants, chief accounting officers, vice presidents of finance, controllers, treasurers, and Big N or national audit firm employees or partners) or finance expertise (i.e., business school faculty, bankers, investment bankers, Certified Financial Analysts, and venture capitalists). We use this definition because companies' required disclosures of designated audit committee financial experts do not include all relevant financial experts (Carcello et al. 2006).

[11] Audit committee independence may also be related to audit committee effectiveness. The average audit committee independence in our post-SOX sample is high (99.4 percent) and shows virtually no variation. Therefore, we do not control for audit committee independence.

[12] Our dichotomous measurement is consistent with Johnson et al. (2002) and Carcello and Nagy (2004). We are unable to use continuous (Geiger and Raghunandan 2002) or decile (Myers et al. 2003) measures as Compustat does not have sufficient details to compute these measures for all audit firms in our sample, and Audit Analytics coverage began in 1999, which implies that Audit Analytics data would only provide truncated measures of auditor tenure.

We also include controls for various company characteristics. First, we control for the presence of large non-director or manager blockholders (*BLOCK*), consistent with Carcello et al. (2006). Large blockholders may play a monitoring role (Shleifer and Vishny 1986) that can serve as a substitute for the audit committee's governance. Thus, we expect the presence of blockholders to be negatively associated with material misstatements being waived. Second, we control for the presence of a CEO who also serves as the chairman of the board (*CEOCOB*). A CEO who serves as the board chair provides less independent corporate oversight (Jensen 1993). Thus, such duality is expected to be positively associated with material misstatements being waived. Next, we control for both the relative size of inventories and receivables (*INVREC*) and firm age (*AGE*), but make no directional predictions for either of these variables. We also control for disclosure of an internal control material weakness (*MW*), litigation risk (*LITRISK*; Francis et al. 1994), recent losses (*LOSS*), company complexity (*SEG*), and growth (*SALESGROWTH*). We make no directional prediction for any of these variables, as they may be positively associated with managers waiving material misstatements because of the risk and complexity that they represent, but auditors may be less likely to allow managers of companies with greater risk and complexity to waive material misstatements. Finally, we control for the size of the company (*ASSETS*) and make no directional prediction for this variable.[13]

Forecast Error: Models 1b and 1c

While we interpret a positive association between analyst following and the qualitative materiality of the misstatement as higher analyst following creating more pressure for managers to meet or beat analyst consensus forecast, an alternative explanation is that companies with higher analyst following may be more likely to meet or just beat analyst consensus forecast because the presence of more analysts creates more accurate consensus forecasts. Thus, results on this variable of interest could be due to a mechanical relation between analyst following and analyst forecast error.[14] To address this alternative explanation, we re-estimate Model 1a using two alternative specifications that include measures of unsigned forecast error (*FE*), along with the interaction of unsigned forecast error with audit fee (*FE* × *FEE*) to ensure that the *ANALYST* × *FEE* interaction is not subject to confounding (Models 1b and 1c). We predict a negative association between forecast error and *QUAL_MATERIAL* because correcting the misstatement should be less likely to cause the company to miss its forecast as forecast error increases in our sample of companies that meet or beat analyst consensus forecast; we make no directional prediction for the *FE* × *FEE* interaction.

We use two measures of forecast error. Our first measure of forecast error is an unscaled version that equals $|[(\text{reported earnings} - \text{waived error}) - \text{consensus forecast}]|$. This measure is *FE_NOSCALE* in Model 1b, and allows us to control for the raw size of the unsigned forecast error. Cheong and Thomas (2011) show that *signed* forecast error does not vary with scale and recommend that researchers consider using unscaled forecast error measures.

Our second measure of forecast error is a version scaled by stock price that equals $|[(\text{reported earnings} - \text{waived error}) - \text{consensus forecast}]/\text{end of year common stock price}| \times 100$. This measure is *FE_SCALED* in Model 1c. *FE_SCALED* allows us to control for the relative size of forecast error, which is likely to be associated with companies' ability to generate similarly large misstatements that exceed forecast error. Scaled forecast error is the predominant measure used in the literature (e.g., Bowen et al. 2002; Eames and Glover 2003).[15] Further, Ball (2011) notes that Cheong and Thomas (2011) only provide empirical support regarding *signed* forecast error and applying their conclusions to *unsigned* forecast error (*FC_NOSCALE*) may not be appropriate in other settings. We use these measures in the following variations of Model 1a:

---

[13] We include industry and year indicator variables in all models. Our industry dummies are consistent with Frankel et al. (2002) and Ashbaugh et al. (2003) except that we add SIC 60-69 to their categories due to the prominence of financial services companies in our sample.

[14] An examination from 2003–2006 of I/B/E/S companies' last analyst consensus forecast before earnings release suggests that unsigned and unscaled forecast error is negatively associated with analyst following ($n = 18{,}401$, $r = -0.20$, $p < 0.001$). While this relation also holds for unsigned and unscaled forecast error ($n = 340$, $r = -0.15$, $p = 0.004$) and unsigned and scaled forecast error ($n = 340$, $r = -0.22$, $p < 0.001$) in our sample, the correlation between analyst following and consensus forecast error is not as large as intuition may suggest.

$$\begin{aligned} QUAL\_MATERIAL = {} & \alpha + \beta_1 ANALYST + \beta_2 FEE + \beta_3 ANALYST \times FEE + \beta_4 ACEXP \\ & + \beta_5 FE\_NOSCALE + \beta_6 FE\_NOSCALE \times FEE + \beta_7 ACMTG \\ & + \beta_8 MIS\_TYPE + \beta_9 TENURE + \beta_{10} BIG\_N + \beta_{11} BLOCK \\ & + \beta_{12} CEOCOB + \beta_{13} INVREC + \beta_{14} AGE + \beta_{15} MW + \beta_{16} LITRISK \\ & + \beta_{17} LOSS + \beta_{18} SEG + \beta_{19} SALESGROWTH + \beta_{20} ASSETS \\ & + \beta_{21} Industry_i + \beta_{22} Year_i + \varepsilon. \end{aligned} \tag{1b}$$

$$\begin{aligned} QUAL\_MATERIAL = {} & \alpha + \beta_1 ANALYST + \beta_2 FEE + \beta_3 ANALYST \times FEE + \beta_4 ACEXP \\ & + \beta_5 FE\_SCALED + \beta_6 FE\_SCALED \times FEE + \beta_7 ACMTG \\ & + \beta_8 MIS\_TYPE + \beta_9 TENURE + \beta_{10} BIG\_N + \beta_{11} BLOCK \\ & + \beta_{12} CEOCOB + \beta_{13} INVREC + \beta_{14} AGE + \beta_{15} MW + \beta_{16} LITRISK \\ & + \beta_{17} LOSS + \beta_{18} SEG + \beta_{19} SALESGROWTH + \beta_{20} ASSETS \\ & + \beta_{21} Industry_i + \beta_{22} Year_i + \varepsilon. \end{aligned} \tag{1c}$$

Models 2 and 3: Quantitative Materiality

We also test H2 and H4 by estimating logit regression models in which the dependent variables include a pretax income measure (Model 2) or a normal income measure (Model 3):

$$\begin{aligned} QUANT\_MATERIAL\_PRETAX = {} & \alpha + \beta_1 FEE + \beta_2 ACEXP + \beta_3 ACMTG + \beta_4 MIS\_TYPE \\ & + \beta_5 TENURE + \beta_6 BIG\_N + \beta_7 BLOCK + \beta_8 CEOCOB \\ & + \beta_9 INVREC + \beta_{10} AGE + \beta_{11} MW + \beta_{12} LITRISK \\ & + \beta_{13} LOSS + \beta_{14} SEG + \beta_{15} SALESGROWTH \\ & + \beta_{16} ASSETS + \beta_{17} Industry_i + \beta_{18} Year_i + \varepsilon. \end{aligned} \tag{2}$$

$$\begin{aligned} QUANT\_MATERIAL\_NORM = {} & \alpha + \beta_1 FEE + \beta_2 ACEXP + \beta_3 ACMTG + \beta_4 MIS\_TYPE \\ & + \beta_5 TENURE + \beta_6 BIG\_N + \beta_7 BLOCK + \beta_8 CEOCOB \\ & + \beta_9 INVREC + \beta_{10} AGE + \beta_{11} MW + \beta_{12} LITRISK \\ & + \beta_{13} LOSS + \beta_{14} SEG + \beta_{15} SALESGROWTH \\ & + \beta_{16} ASSETS + \beta_{17} Industry_i + \beta_{18} Year_i + \varepsilon. \end{aligned} \tag{3}$$

For each year a misstatement is present during our sample period, we identify the amount of the misstatement on the balance sheet and on the income statement. Consistent with the dual approach required by SAB 108, we calculate the quantitative materiality of misstatements in year *t* using the greater of these two amounts.

Quantitative materiality can be measured using various thresholds (Brody et al. 2003), but 5 percent of pretax income is the most common measure for public companies (Leslie 1985; Messier et al. 2005). Therefore, we first estimate the quantitative materiality of misstatements as 5 percent of pretax income, *QUANT_MATERIAL_PRETAX*. Note, however, a pretax income measure is less appropriate when companies report net losses or breakeven results, because materiality cannot be negative in a net loss year or almost zero in a breakeven year (Leslie 1985). To address this issue, we omit observations with current-year losses and small profits that are less than 1 percent of total assets when using *QUANT_MATERIAL_PRETAX* as our dependent variable.

---

[15] We performed a search for studies that include measures of forecast error for each of the last ten years in *The Accounting Review*, *Journal of Accounting Research*, *The Journal of Accounting and Economics*, and *Contemporary Accounting Research*. The search yielded 40 articles, each of which uses some variation of a scaled forecast error variable, almost always scaled by stock price. Therefore, the overwhelming pattern in the literature is to use a stock-price scaled forecast error variable.

We next estimate the quantitative materiality of misstatements as 5 percent of pretax normal income, *QUANT_MATERIAL_NORM*.[16] This approach allows us to use all of the observations in our sample without removing loss and small-profit observations. Leslie (1985, 30) reports a study that finds that the materiality decisions of companies with loss and breakeven results are "within 5% to 10% of what might be considered normal net income, based on return on stockholders' equity." Following Leslie (1985), we estimate the "normal income" of our sample companies as the greatest of the industry return on equity (*ROE*) multiplied by the company's stockholders' equity, the *ROE* of 1 percent for companies in the overall market multiplied by the company's stockholders' equity, or the company's reported pretax income.[17] All other variables in Models 2 and 3 are as previously defined for Model 1a.

IV. RESULTS

Descriptive Statistics

Table 3, Panel A compares companies waiving qualitatively material versus qualitatively immaterial misstatements. Results show that companies waiving qualitatively material misstatements have lower audit fees (*LNAUDIT*: $p = 0.01$), lower abnormal audit fees (*ABNORMALAUDIT*: $p = 0.01$), and audit fees that are marginally less important to the auditor's local office or firm portfolio (*OFFICEAUDIT*: $p = 0.09$; *FIRMAUDIT*: $p = 0.10$), as compared to companies waiving qualitatively immaterial misstatements. Companies waiving qualitatively material misstatements also have fewer audit committee financial experts (*ACEXP*: $p < 0.01$), have lower absolute and relative forecast errors (*FE_NOSCALE*: $p < 0.01$; *FE_SCALED*: $p < 0.01$), are marginally more likely to have misstatements involving complex accounting judgments (*MIS_TYPE*: $p = 0.09$), have higher relative inventories and receivables (*INVREC*: $p = 0.02$), and are marginally less likely to report a recent loss (*LOSS*: $p = 0.08$).

Table 3, Panels B and C compare quantitatively material to quantitatively immaterial misstatements by splitting the groups based on *QUANT_MATERIAL_PRETAX* (Panel B) and *QUANT_MATERIAL_NORM* (Panel C). Results are similar across the two panels and show that companies waiving quantitatively material misstatements have lower audit fees (*LNAUDIT*: $p < 0.01$ and $p < 0.01$ in Panels B and C, respectively) and audit fees that are less important to

---

[16] Gleason and Mills (2002) define normal income as the greater of a company's pretax income or 5 percent of assets, where 5 percent of assets is the median pretax return on assets for their 100 large manufacturing companies over a nine-year period.

[17] More specifically, we use the Compustat database to identify the yearly median *ROE* for the industry of each company within our sample. We define a company's industry at the two-digit SIC code level. We calculate *ROE* as Compustat pretax income (pi)/total stockholders' equity (seq). This measure can be used to approximate a company's normal income by multiplying the applicable *ROE* by stockholders' equity unless the industry has been depressed during the period. In the case of an industry-wide market downturn, Leslie (1985, 31) recommends using a "rate of return on equity as compared with all business in general." In untabulated analysis we estimate the median *ROE* for U.S. companies to be 1.3 percent, 1.7 percent, 1.8 percent, and 1.9 percent for 2003, 2004, 2005, and 2006, respectively. The overall median *ROE* for U.S. companies across our sample period is 1.6 percent. To be conservative, we define *ROE* as 1.0 percent for companies in the overall market during our sample period.

[a] Quantitatively material misstatements refers to *QUANT_MATERIAL_NORM* = 1. Quantitatively immaterial misstatements refers to *QUANT_MATERIAL_NORM* = 0.
[b] Variable definitions are in Table 2.
[c] Continuous variable statistics are t-statistics from means tests. Indicator variable statistics are Chi-Squares with continuity corrections. All p-values are two-tailed.

the auditor's local office or firm portfolio (*OFFICEAUDIT*: $p < 0.01$ and $p = 0.04$; *FIRMAUDIT*: $p < 0.01$ and $p = 0.04$), as compared to companies waiving quantitatively immaterial misstatements. Companies waiving quantitatively material misstatements also have fewer audit committee meetings (*ACMTG*: $p < 0.01$ and $p < 0.01$), are more likely to have misstatements involving complex accounting judgments (*MIS_TYPE*: $p < 0.01$ and $p < 0.01$), have shorter relationships with their audit firm (*TENURE*: $p < 0.01$ in Panel C only), are less likely to be audited by a Big 4 auditor (*BIG_N*: $p < 0.01$ in Panel C only), are more likely to have large blockholders (*BLOCK*: $p < 0.01$ and $p < 0.01$), have lower relative inventories and receivables (*INVREC*: $p < 0.01$ and $p < 0.01$), and are younger (*AGE*: $p = 0.09$ and $p < 0.01$). Further, companies waiving quantitatively material misstatements are more likely to be in a litigious industry (*LITRISK*: $p < 0.01$ and $p = 0.01$), are more likely to experience a loss (*LOSS*: $p < 0.01$ and $p < 0.01$), have lower sales growth (*SALESGROWTH*: $p = 0.01$ and $p = 0.03$), and are smaller in terms of assets (*ASSETS*: $p < 0.01$ and $p < 0.01$), as compared to companies waiving immaterial misstatements.

In untabulated analyses, the correlations among the independent variables for Models 1a–1c, Model 2, and Model 3 are relatively low. The only exceptions are the correlations between company size (*ASSETS*) and the measures for audit fees (*FEE*) and analyst following (*ANALYST*), which are consistently above 0.50. However, collinearity does not appear to be an issue in any of the hypothesis-testing models. The variance inflation factors (VIFs) from linear regressions are all consistently well below the 10.00 cutoff suggested by Belsley et al. (1980).

Model 1: Qualitative Materiality Tests (*QUAL_MATERIAL*)

H1 predicts that analyst following increases the likelihood that managers will waive material misstatements.[18] Consistent with this expectation, the *ANALYST* coefficient across Models 1a–1c in

---

[18] We estimate the models in Tables 4 and 5 and all robustness tests using robust standard errors clustered by company. We also winsorize all continuous variables at the 1st and 99th percentiles.

Panels A, C, E, and G of Table 4 generally shows a positive one-tailed association between analyst following and the likelihood of managers waiving a qualitatively material misstatement in models in which the independent variable is the level of audit fees (*LNAUDIT*: $p = 0.04$, $p = 0.09$, $p = 0.04$, respectively), abnormal audit fees (*ABNORMALAUDIT*: $p = 0.05$, $p = 0.11$, $p = 0.04$, respectively), the office rank of audit fees (*OFFICEAUDIT*: $p = 0.04$, $p = 0.05$, $p = 0.05$, respectively), and the firm rank of audit fees (*FIRMAUDIT*: $p = 0.03$, $p = 0.08$, $p = 0.05$, respectively). Overall, *ANALYST* is statistically significant in models when we do not control for forecast error or control for scaled forecast error (*FE_SCALED*) and is weaker or marginal when we control for unscaled forecast error (*FE_NOSCALE*).

It is important to note, however, that the coefficient on *ANALYST* only tests the association between analyst following and the dependent variable conditional on mean-centered audit fees being zero because *ANALYST* is interacted with *FEE*.[19] This association may be different across levels of *FEE* because the marginal effect of *ANALYST* is the partial derivative with respect to *ANALYST* and considers the interaction term with *FEE*. To provide greater insight on the main effect of *ANALYST*, we examine the marginal effects of a one-unit change in *ANALYST* on a change in the probability of managers waiving a qualitatively material misstatement at three levels of *FEE*: at the mean, at the mean less one standard deviation (i.e., relatively low), and at the mean plus one standard deviation (i.e., relatively high). See Panels B, D, F, and H in Table 4.[20] These analyses show that the main effect of *ANALYST* is strongest when audit fees are relatively low and is weakest when audit fees are relatively high. For example, increasing analyst following in Model 1a by one unit is associated with an increase of 18 percent ($p < 0.01$) in the likelihood of waiving a qualitatively material misstatement when *LNAUDIT* is relatively low, but increasing analyst following by one unit is associated with a zero percent ($p = 0.43$) increase in the likelihood of waiving a qualitatively material misstatement when *LNAUDIT* is relatively high. Taken together, these results generally show that analyst following is positively associated with the probability of managers waiving a qualitatively material misstatement, and this association is primarily present when audit fees are relatively low.[21] However, these results must be interpreted in light of the interaction between analyst following and audit fees, which we discuss below.

H2 predicts that audit fees affect the likelihood that auditors will allow managers to waive material misstatements. The results across Models 1a–1c in Panels A, C, E, and G of Table 4 generally show a negative association between audit fees and the likelihood of managers waiving a qualitatively material misstatement in models in which the independent variable is the level of audit fees (*LNAUDIT*: $p < 0.01$, $p = 0.03$, $p = 0.01$, respectively), abnormal audit fees (*ABNORMALAUDIT*: $p < 0.01$, $p = 0.01$, $p = 0.01$, respectively), the office rank of audit fees (*OFFICEAUDIT*: $p = 0.25$, $p = 0.06$, $p = 0.05$, respectively), and the firm rank of audit fees (*FIRMAUDIT*: $p = 0.10$, $p = 0.05$, $p = 0.02$, respectively). These results generally show that audit

---

[19] With regard to interpreting the coefficient for a variable that is also in the interaction, Jaccard (2001, 20) notes that "[a] common mistake . . . is to interpret this coefficient as if it represents a nonconditioned main effect." In other words, the coefficient for *ANALYST* represents the effect of *ANALYST* on *QUAL_MATERIAL* when mean-centered audit fees are zero.

[20] A marginal effect of 50 percent or 0.50 in a nonlinear model is most accurately interpreted as "y increases with x at a rate such that, if the rate were constant, y would increase by 0.5 if x increased by 1" (Stata 2009, 977). All marginal effects and p-values are calculated at the mean of the variable of interest using the Stata 11 margins command with the dydx option that appropriately recognizes when a covariate is used in a product term (e.g., *ANALYST* and *ANALYST* × *FEE*). This command uses the actual observation-level values of covariates unless otherwise specified and calculates the marginal effects using the sample average of individual marginal effects, which is the method favored in current practice (Greene 2008, 775).

[21] The exception is in the model using *OFFICEAUDIT* as the measure of audit fees. In that case, the main effect of *ANALYST* is significant at higher levels of audit fees and, as we discuss subsequently, we do not find evidence of an *ANALYST* × *OFFICEAUDIT* interaction.

Pseudo R^2				0.28			0.30			0.32

Dependent variable, *QUAL_MATERIAL*, equals 1 if company reported basic EPS that meet or beat last analysts' median consensus forecast before earnings report, but would have missed the forecast if it corrected the income statement misstatement, 0 otherwise. All standard errors are clustered by company.

[a] Variable definitions are in Table 2. *ANALYST*, *FEE*, *FE_NOSCALE*, and *FE_SCALED* are mean centered.

[b] All p-values are two-tailed, except for those variables with directional expectations. Economic effects for continuous independent variables represent the effect of a one standard deviation increase from the mean (including adjusting the interaction term) has on the predicted probability of the dependent variable being 1 and for indicator variables represent the effect a change from 0 to 1 has on the predicted probability of the dependent variable being 1. The calculations include the constant, as well as all other model variables at their means (Long and Freese 2005). The economic effect for the interaction term represents the effect of a one standard deviation increase from the mean in both *ANALYST* and *FEE*, as well as the associated increase in the interaction of the two terms. The calculations include the constant, as well as all other model variables at their means.

[c] *FEE* denotes mean-centered *LNAUDIT*, *ABNORMALAUDIT*, *OFFICEAUDIT*, and *FIRMAUDIT*, respectively.

Industry$_j$ and *Year*$_i$	NA									
Qualitatively material n				40			40			40
Qualitatively immaterial n				300			300			300
Pseudo R^2				0.24			0.27			0.30

Dependent variable, *QUAL_MATERIAL*, equals 1 if company reported basic EPS that meet or beat last analysts' median consensus forecast before earnings report, but would have missed the forecast if it corrected the income statement misstatement, 0 otherwise. All standard errors are clustered by company.

[a] Variable definitions are in Table 2. *ANALYST*, *FEE*, *FE_NOSCALE*, and *FE_SCALED* are mean centered.

(continued on next page)

TABLE 4 (continued)

[b] All p-values are two-tailed, except for those variables with directional expectations. Economic effects for continuous independent variables represent the effect of a one standard deviation increase from the mean (including adjusting the interaction term) has on the predicted probability of the dependent variable being 1 and for indicator variables represent the effect a change from 0 to 1 has on the predicted probability of the dependent variable being 1. The calculations include the constant, as well as all other model variables at their means (Long and Freese 2005). The economic effect for the interaction term represents the effect of a one standard deviation increase from the mean in both *ANALYST* and *FEE*, as well as the associated increase in the interaction of the two terms. The calculations include the constant, as well as all other model variables at their means.

[c] *FEE* denotes mean-centered *LNAUDIT*, *ABNORMALAUDIT*, *OFFICEAUDIT*, and *FIRMAUDIT*, respectively.

Panel H: Marginal Effect of *ANALYST* for *FIRMAUDIT* as *FEE* Models

	Model 1a No Control for Forecast Error		**Model 1b *FE_NOSCALE***		**Model 1c *FE_SCALED***	
	Marg.	**p**	**Marg.**	**p**	**Marg.**	**p**
FEE = Mean − 1 sd	17%	0.02	17%	0.04	12%	0.01
FEE = Mean	7%	0.03	6%	0.05	6%	0.01
FEE = Mean + 1 sd	1%	0.40	0%	0.92	2%	0.59
Interaction Effect Analyses						
Percent of neg. int. effects		99%		97%		96%
1 sd decrease in *FEE* from mean at *ANALYST* mean		8%		10%		7%
1 sd decrease in *FEE* from mean at *ANALYST* mean plus 1 sd		27%		27%		26%

fees are negatively associated with the probability of managers waiving a qualitatively material misstatement. Again, these results must be interpreted in light of the interaction between analyst following and audit fees, which we discuss below.

H3 predicts the interaction between analyst following and audit fees. The results across Models 1a–1c in Panels A, C, E, and G of Table 4 are consistent with a negative interaction between analyst following and audit fees in models in which the independent variable is the level of audit fees (*LNAUDIT*: $p = 0.05$, $p = 0.11$, $p = 0.10$, respectively), abnormal audit fees (*ABNORMALAUDIT*: $p = 0.05$, $p = 0.03$, $p = 0.05$, respectively), and the firm rank of audit fees (*FIRMAUDIT*: $p = 0.06$, $p = 0.12$, $p = 0.08$, respectively), but not the office rank of audit fees (*OFFICEAUDIT*: $p = 0.50$, $p = 0.55$, $p = 0.53$, respectively). However, Ai and Norton (2003) and Greene (2010) demonstrate that the coefficient on an interaction term is the "partial interaction," such that its significance should not be interpreted as necessarily indicative of the presence or absence of an interaction effect.[22]
